

# **ASSESSMENT OF TRANSMISSION CONGESTION IMPACTS ON ELECTRICITY MARKETS**

**presentation by**

**George Gross**

**Department of Electrical and Computer Engineering**

**University of Illinois at Urbana-Champaign**

**University Of New South Wales**

**Kensington, Australia**

**September 23, 2004**

# OUTLINE

---

- ❑ **Transmission-unconstrained markets**
- ❑ **Transmission-constrained markets**
- ❑ **Market performance metrics**
- ❑ **Measures of congestion impacts**
- ❑ **Congestion and local market power**
- ❑ **Congestion impact evaluation examples in various systems**

# THE TIME FRAME FOR MARKETS

- We define one hour as the smallest indecomposable unit of time and focus on a specified hour  $h$
- We discuss the market decisions for that specified hour

# THE CENTRALIZED ELECTRICITY MARKET (CEM)

- We discuss the structure of the forward market by examining the day-ahead centralized electricity market
- In fact, the day-ahead market is a collection of 24 separate commodity markets, one for each hour of the day; we focus on the market corresponding to the specified hour  $h$  and suppress the hour  $h$  in our notation

# CEM STRUCTURE

# CEM PARTICIPANTS

---

- The CEM *operator* is in charge of this market and uses auctions to determine the prices and quantities bought and sold for each hour**
- Sellers are generation entities and brokers/marketers**
- Buyers are consumers, brokers/marketers, distribution entities and generation entities**

# THE COMPETITIVE ELECTRICITY MARKET

---

- ❑ **Sellers and buyers in the market submit sealed offers and bids, respectively, describing the price and quantity at which they are willing to sell/buy energy**
- ❑ **The CEM operator determines the successful offers and bids and the market clearing price by maximizing the social surplus**
- ❑ **The auction results determine the unit commitment and dispatch of the physical units**

# SELLER $i$ OFFER AND COSTS

# BUYER $j$ BID AND BENEFITS

# THE SOCIAL WELFARE

The social welfare is defined as the total benefits of the buyers minus the total costs of the sellers:

The diagram illustrates the definition of social welfare. It features a central equation:  $\mathcal{S} \triangleq \sum_{j=1}^N \mathcal{B}_j(P^{B_j}) - \sum_{i=1}^M \mathcal{C}_i(P^{S_i})$ . The first term,  $\sum_{j=1}^N \mathcal{B}_j(P^{B_j})$ , is enclosed in an orange rounded rectangle and is connected by a line to a callout box labeled "total benefits" in orange text. The second term,  $\sum_{i=1}^M \mathcal{C}_i(P^{S_i})$ , is enclosed in a green rounded rectangle and is connected by a line to a callout box labeled "total costs" in green text. A blue callout box labeled "social welfare" is connected to the symbol  $\mathcal{S}$  on the left side of the equation.

$$\mathcal{S} \triangleq \sum_{j=1}^N \mathcal{B}_j(P^{B_j}) - \sum_{i=1}^M \mathcal{C}_i(P^{S_i})$$

social welfare

total benefits

total costs

# MAXIMIZATION OF THE SOCIAL WELFARE

---

- ❑ The objective in markets is to maximize the social welfare, so as to determine the maximum net benefits for society
- ❑ We neglect the transmission network constraints
- ❑ The CEM *operator* solves the resulting optimization problem to determine the successful offers and bids

$$\max \quad \mathcal{S} = \sum_{j=1}^N \mathcal{B}_j(p_{B_j}) - \sum_{i=1}^M \mathcal{C}_i(p_{S_i})$$

*s.t.*

$$\sum_{j=1}^N p_{B_j} = \sum_{i=1}^M p_{S_i} \quad \text{supply-demand balance}$$

# MAXIMIZATION OF THE SOCIAL WELFARE

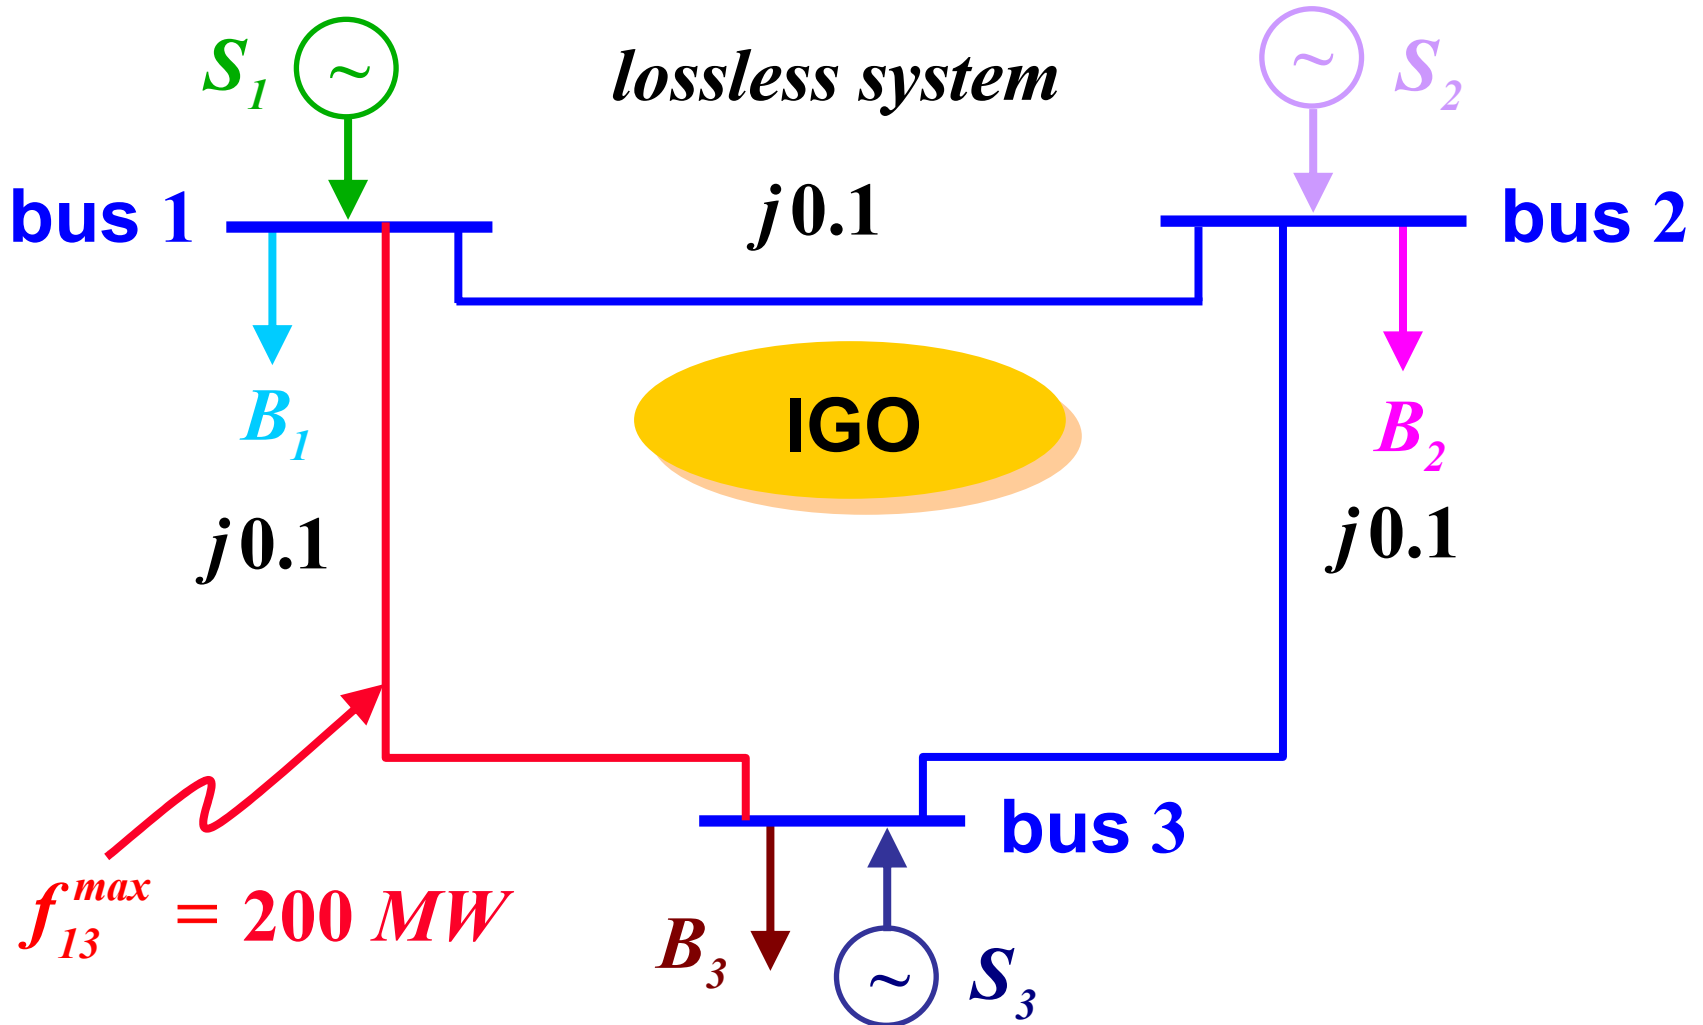

# MARKET CLEARING PRICE

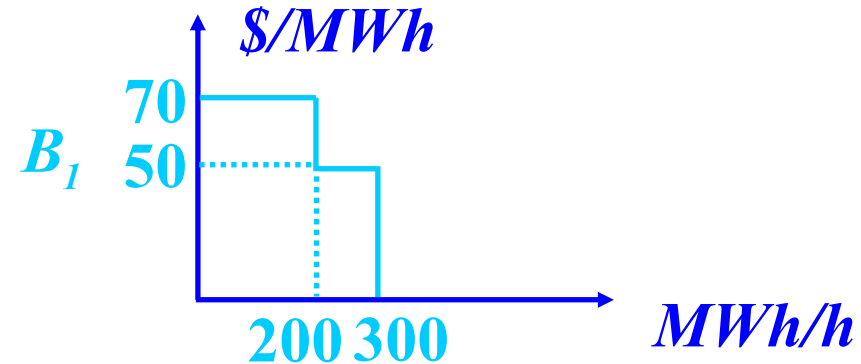

---

- ❑ The market clearing price  $\rho^*$  (system marginal price) is the change in the social welfare for a unit change in the market clearing quantity
- ❑ Each seller receives  $\rho^*$  from the CEM operator for each *MWh* sold
- ❑ Each buyer pays  $\rho^*$  to the CEM for each *MWh* bought
- ❑ The market clearing price is different from the offer/bid price of *nearly* every player

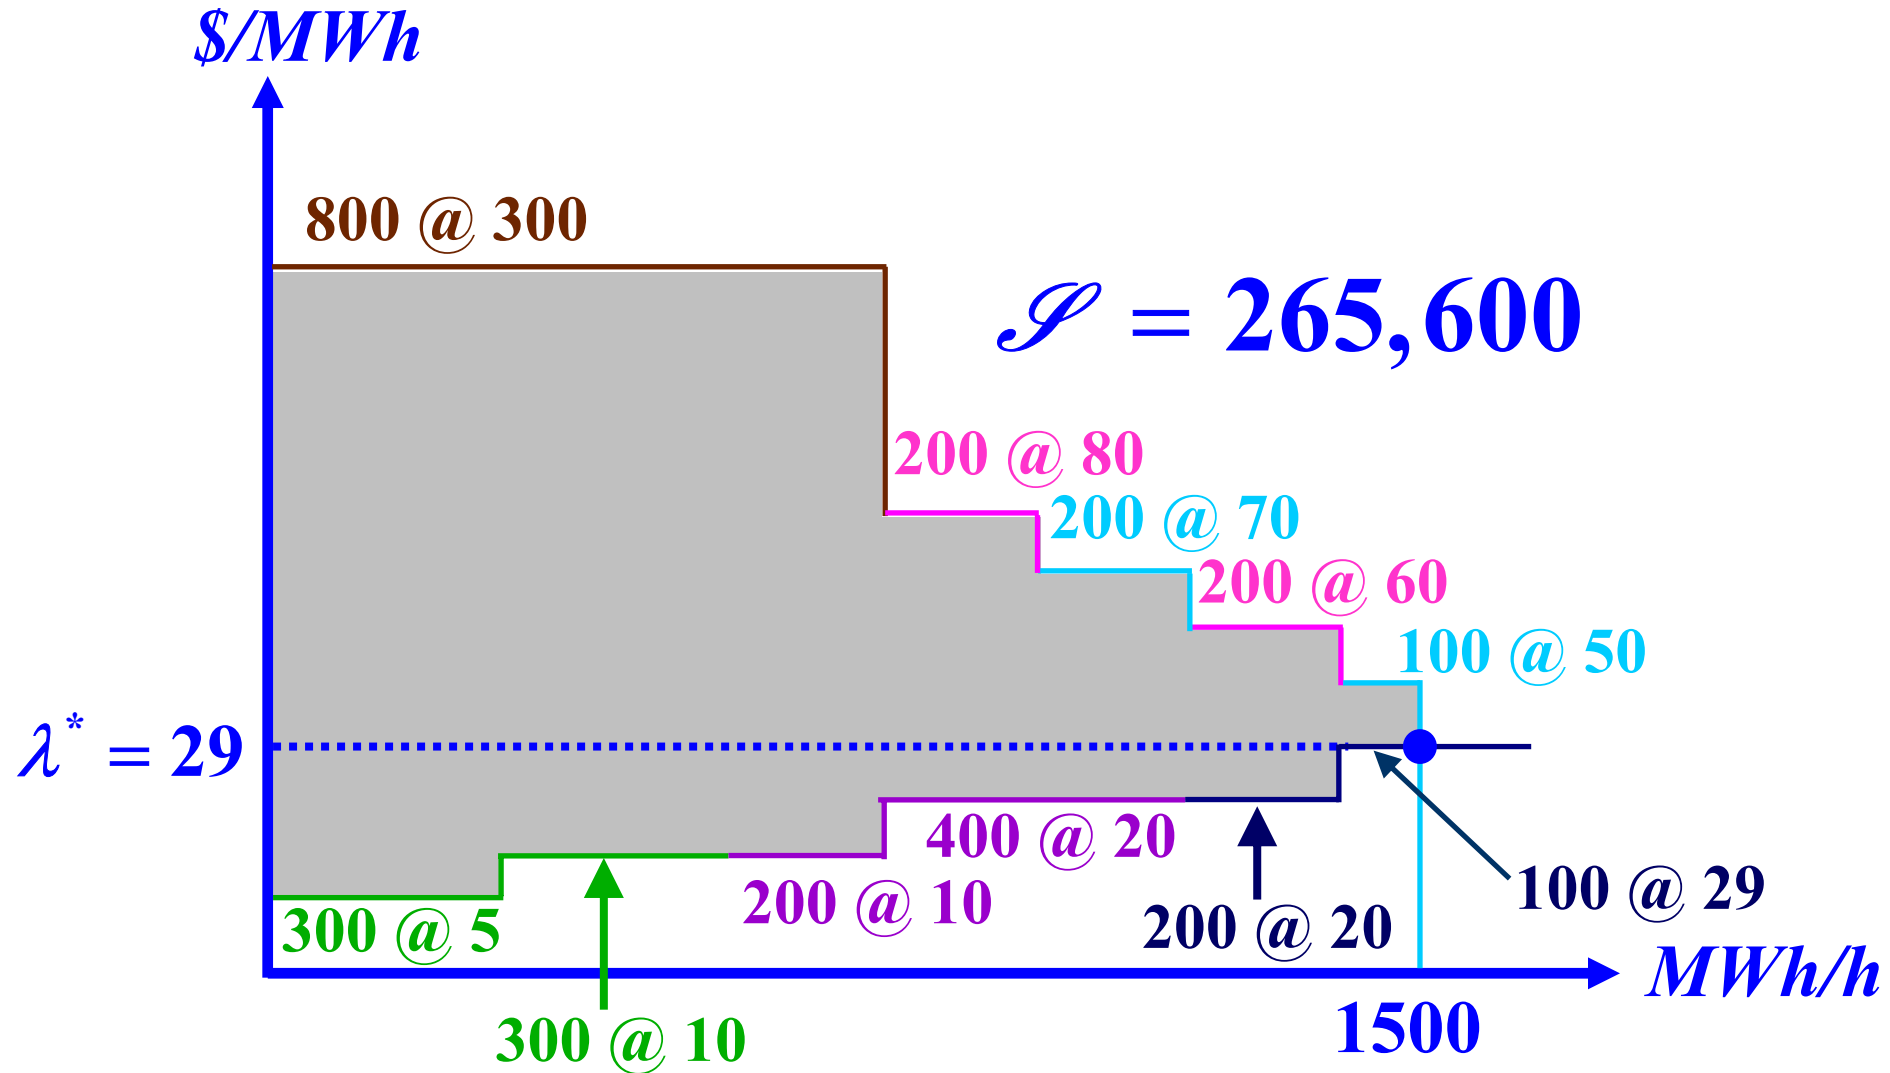

# THE THREE-BUS SYSTEM EXAMPLE

# THREE-BUS SYSTEM: OFFERS AND BIDS

# THREE-BUS SYSTEM: TRANSMISSION UNCONSTRAINED EQUILIBRIUM

# UNCONSTRAINED SYSTEM REVENUES AND PAYMENTS

---

| participant | quantity [MWh] | price [\$/MWh] | revenue [\$] | payments [\$] |
|-------------|----------------|----------------|--------------|---------------|
| <i>S1</i>   | 600            | 29             | 17400        | -             |
| <i>S2</i>   | 600            | 29             | 17400        | -             |
| <i>S3</i>   | 300            | 29             | 8700         | -             |
| <i>B1</i>   | 300            | 29             | -            | 8700          |
| <i>B2</i>   | 400            | 29             | -            | 11600         |
| <i>B3</i>   | 800            | 29             | -            | 23200         |
| total       | 1500           | 29             | 43500        | 43500         |

# MARKET PERFORMANCE BASIC MEASURES

---

- The social welfare is a measure of the performance of the market as a whole but it does not provide insights about the performance of the individual players
  
- We define two components of social welfare
  - producer surplus
  
  - consumer surplus

# PRODUCER SURPLUS

- For a seller  $i$ , the *individual producer surplus* measures the difference between the revenues received for the sale at the *market clearing price* and those that would be received at the offer price

$$\mathcal{P}_i^S = \underbrace{\rho^* \cdot p_{S_i}}_{\text{revenues under } \rho^*} - \underbrace{c_i(p_{S_i})}_{\text{revenues under offer}} \quad i = 1, \dots, M$$

revenues  
under  $\rho^*$

revenues  
under offer

- The total *producer surplus* is

$$\mathcal{P}^S = \sum_{i=1}^M \mathcal{P}_i^S$$

# CONSUMER SURPLUS

- For each buyer  $j$ , the *individual consumer surplus* measures the difference between the payments for the commodity at the bid prices of the buyer and those at the *market clearing price*

$$\mathcal{S}_j^B = \underbrace{\mathcal{B}_j(p_{B_j})}_{\text{actual benefits}} - \underbrace{\rho^* \cdot p_{B_j}}_{\text{payments with } \rho^*} \quad j = 1, \dots, N$$

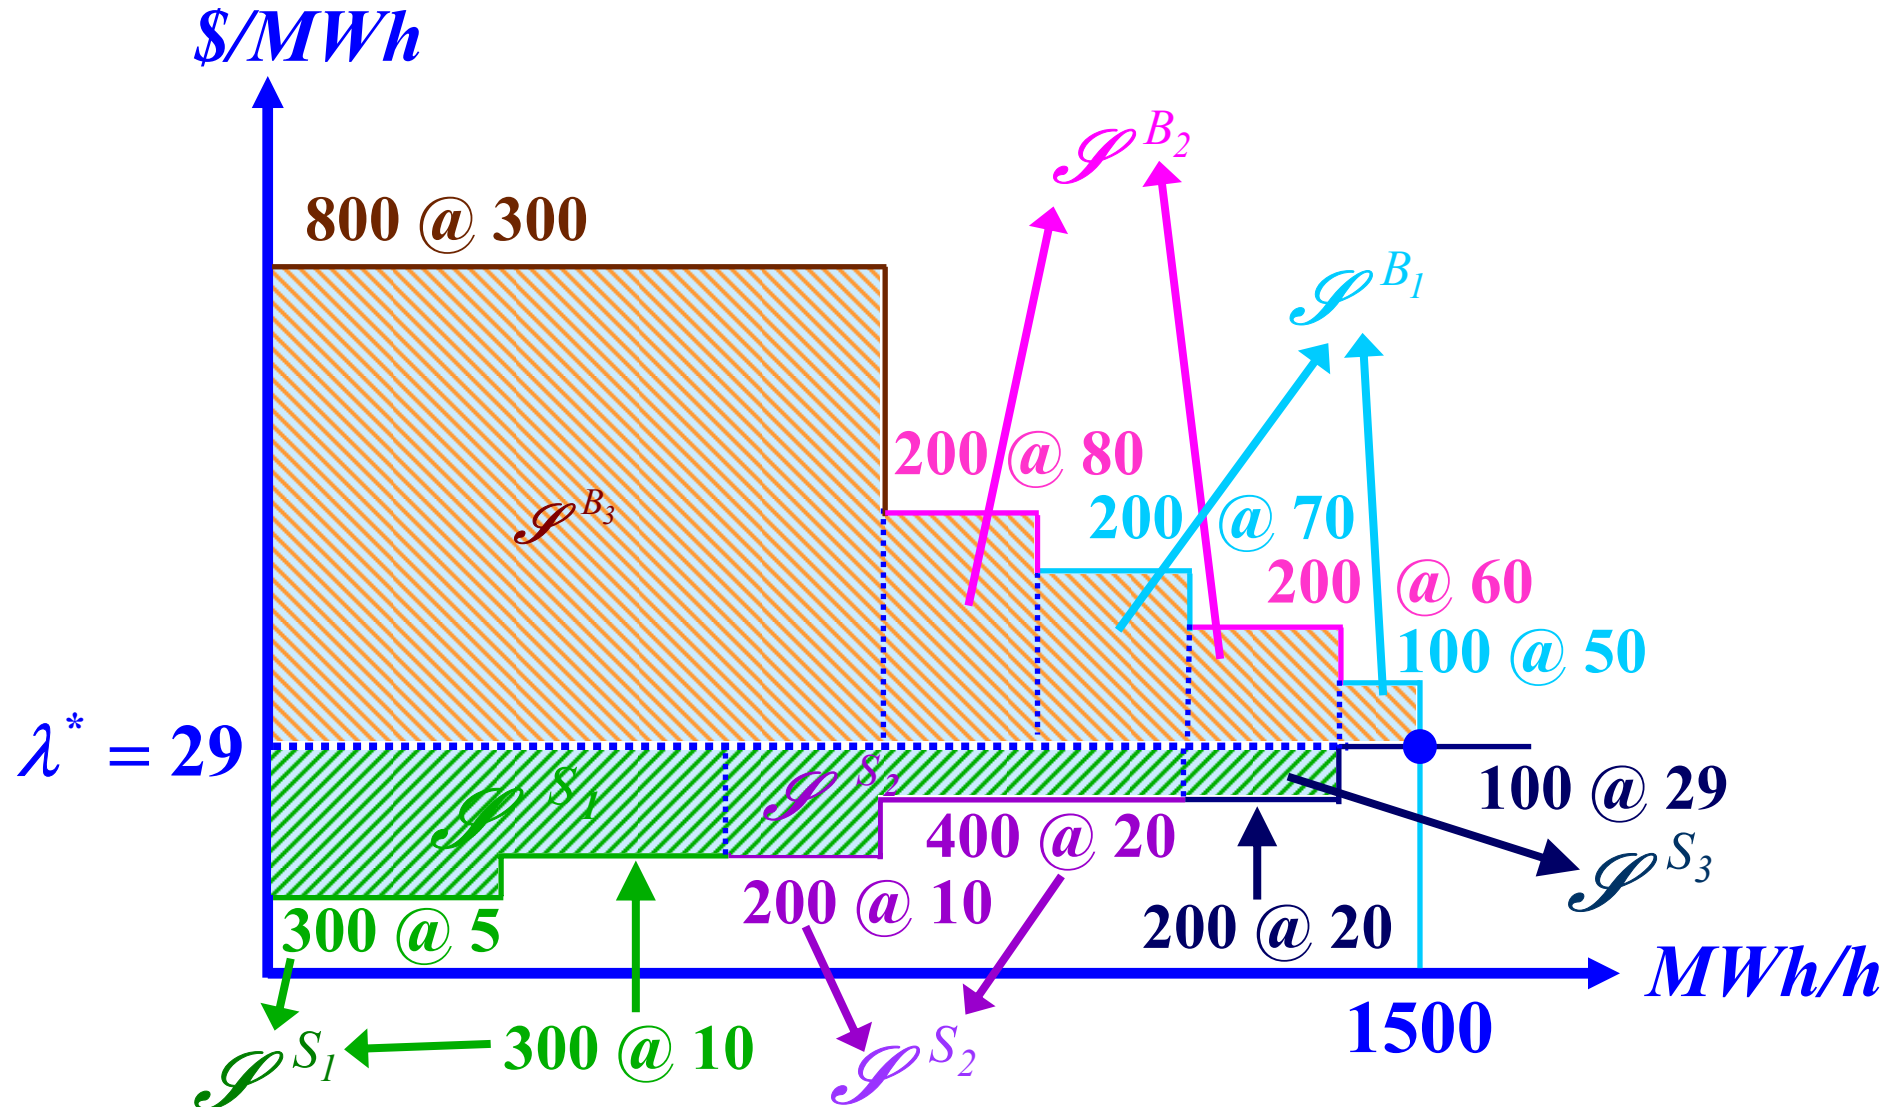

actual  
benefits

payments  
with  $\rho^*$

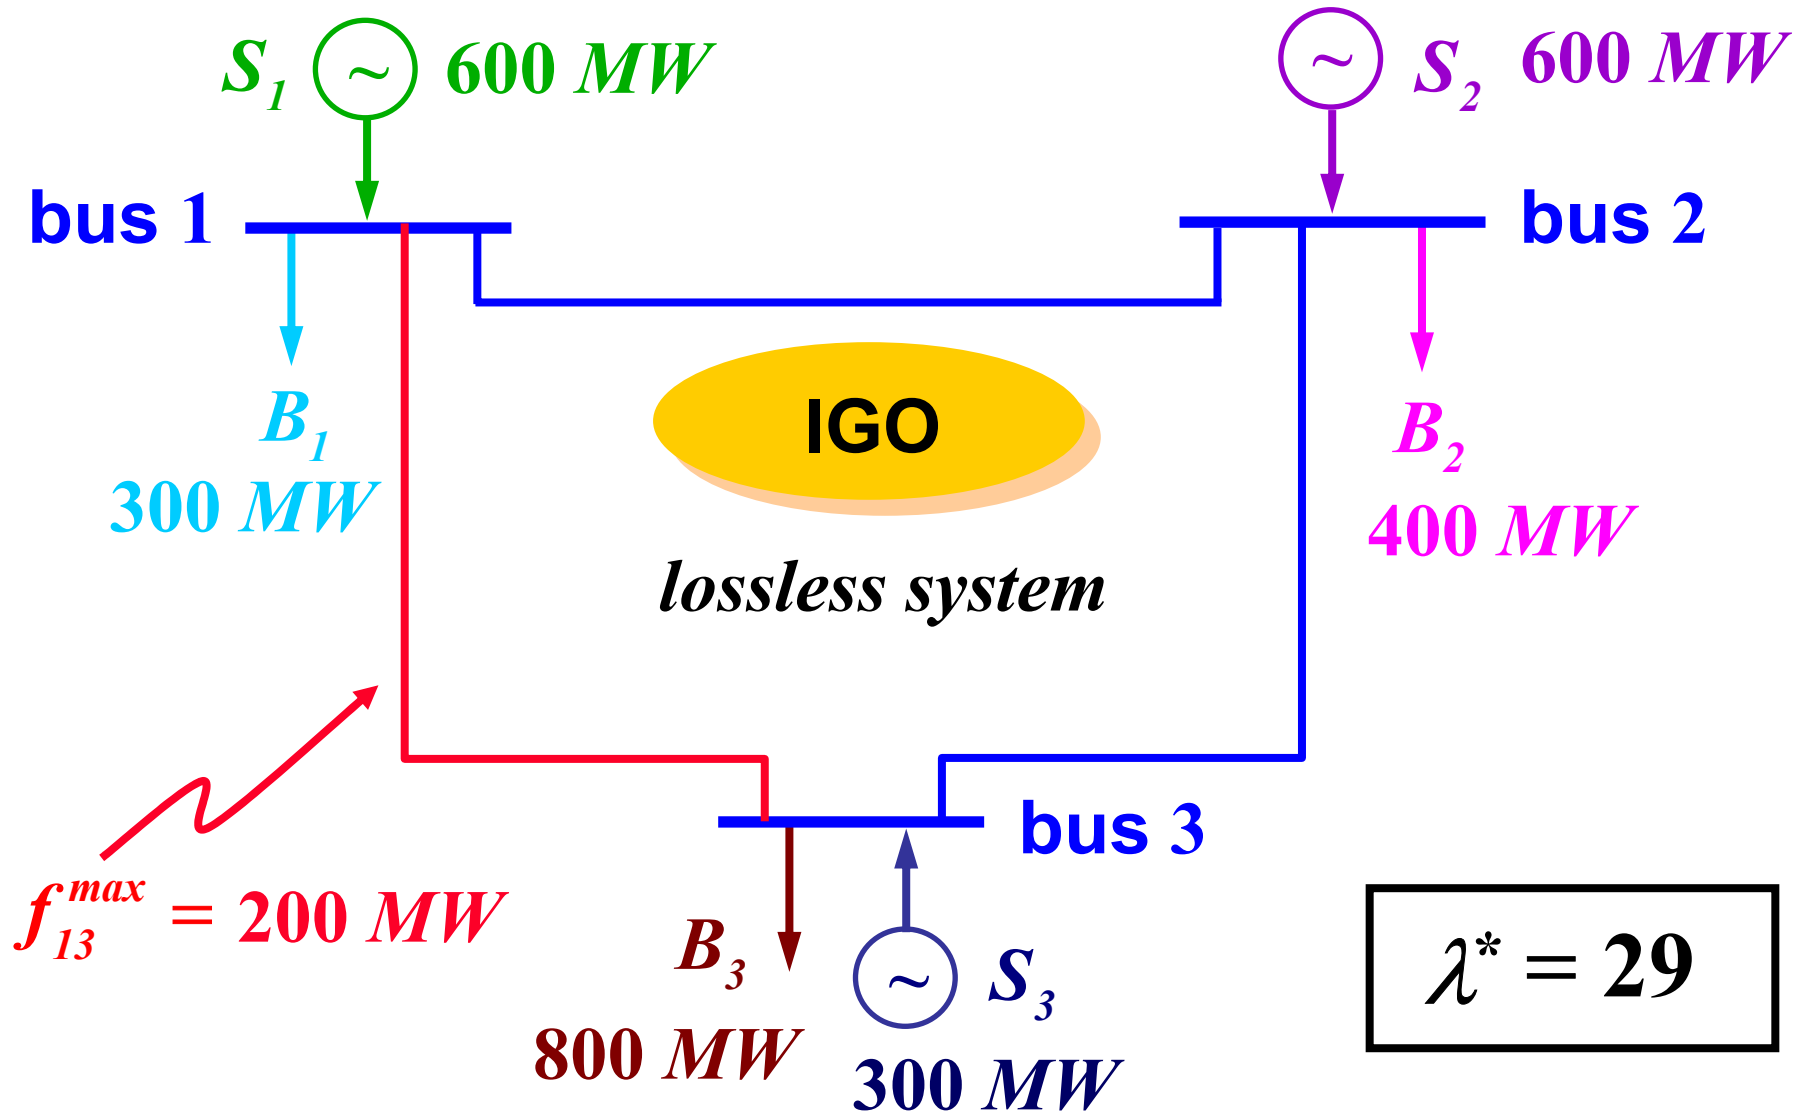

- The total *consumer surplus* is

$$\mathcal{S}^B = \sum_{j=1}^N \mathcal{S}_j^B$$

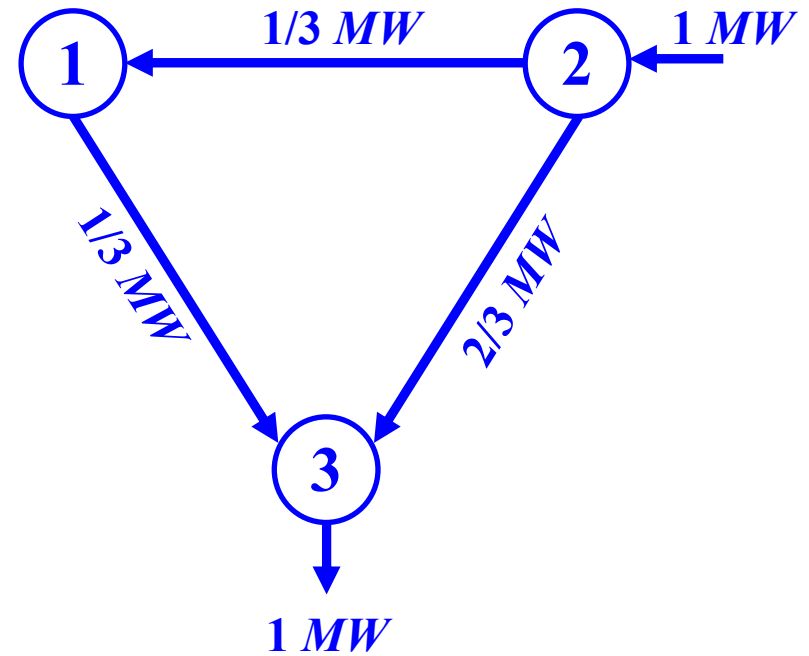

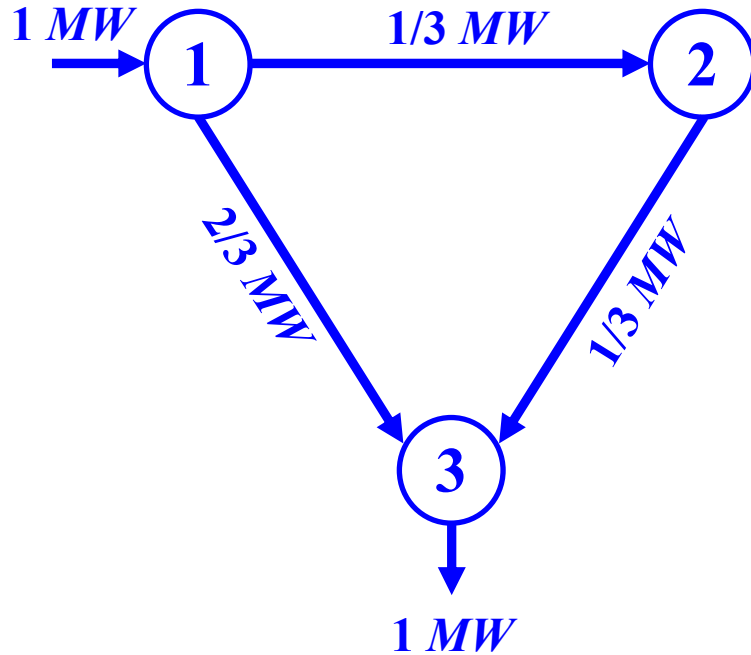

# THREE-BUS SYSTEM: TRANSMISSION UNCONSTRAINED EQUILIBRIUM

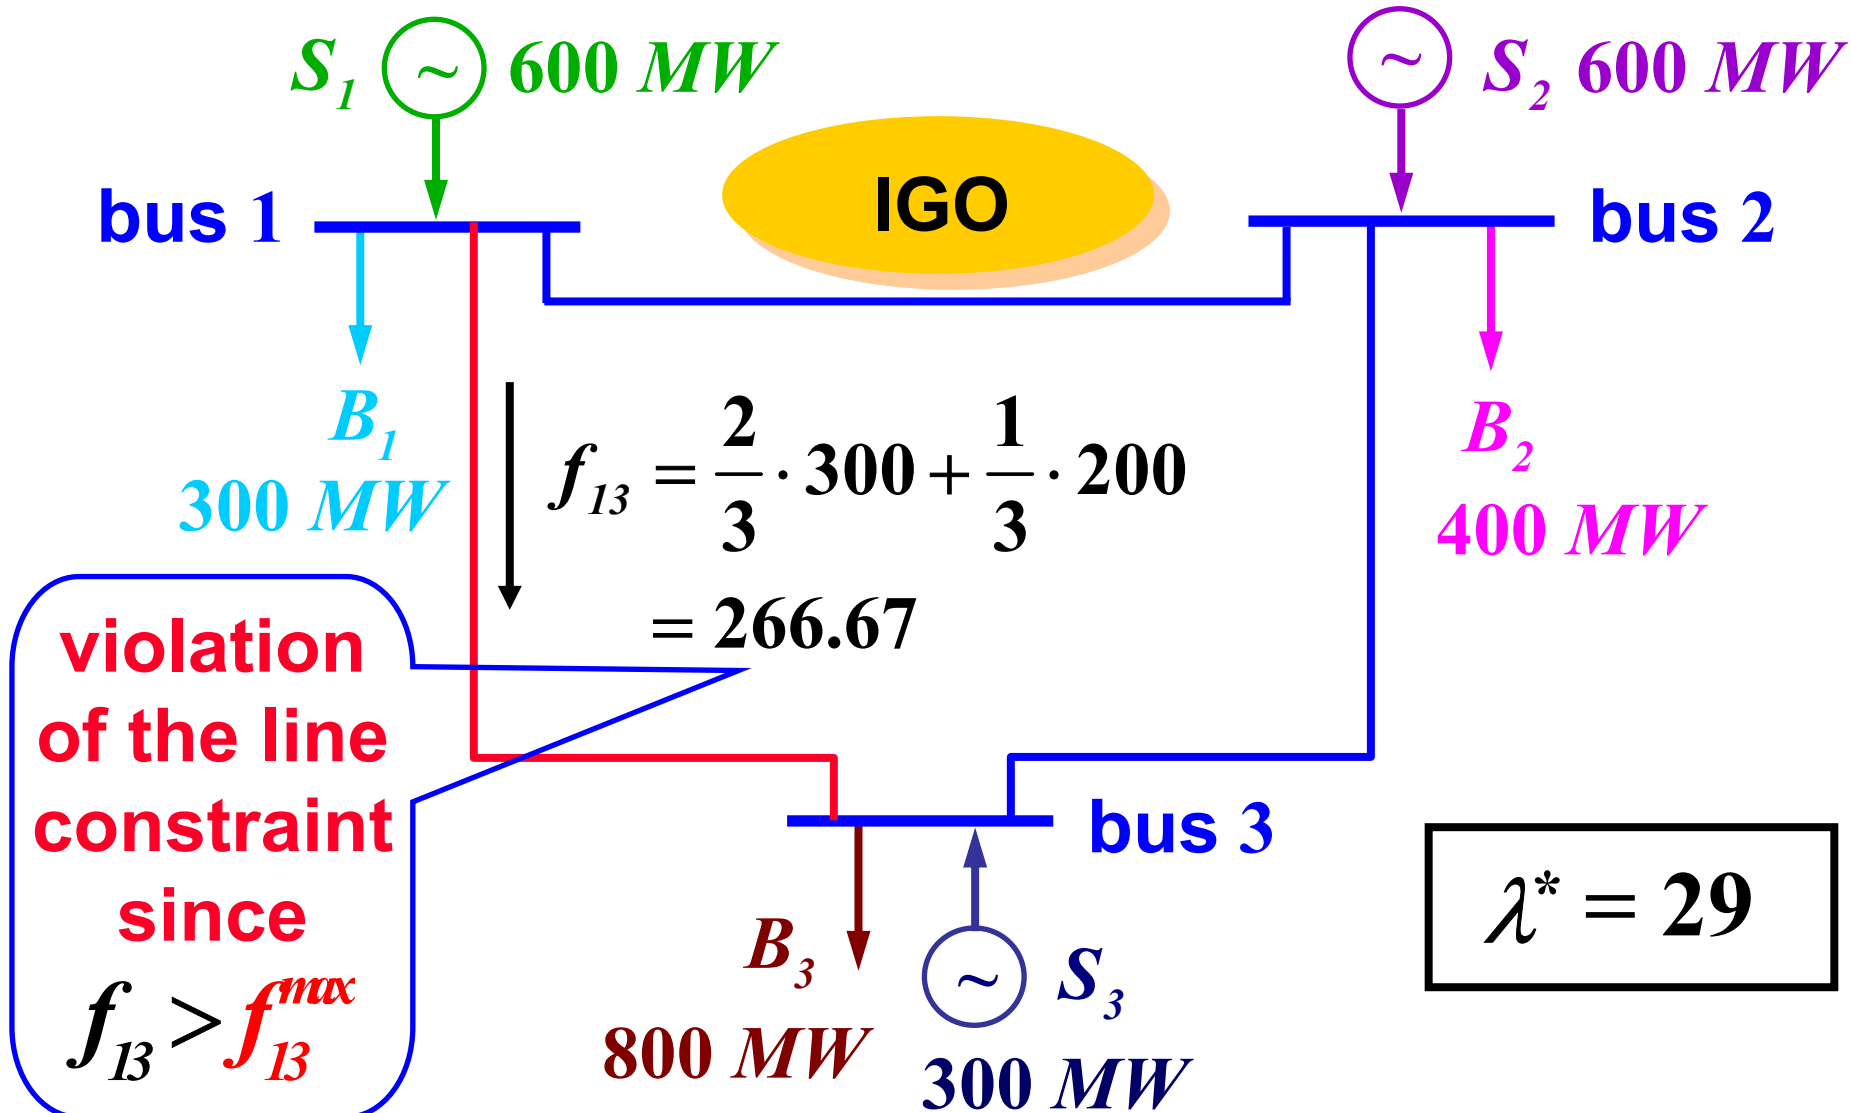

# THREE-BUS SYSTEM: TRANSMISSION UNCONSTRAINED DISPATCH

# THREE-BUS SYSTEM: PTDFs

# THREE-BUS SYSTEM: TRANSMISSION UNCONSTRAINED DISPATCH

# THREE-BUS SYSTEM: TRANSMISSION UNCONSTRAINED DISPATCH

---

- ❑ The transmission unconstrained dispatch is infeasible because the line flow  $f_{13}$  violates limit  $f_{13}^{max}$
- ❑ The net injections at buses 1 and 2 have to be modified to drive the network to feasibility
- ❑ The only choice of buyer  $B_3$  is to bid sufficiently high to induce seller  $S_3$  to provide supply to meet his load

# SOCIAL WELFARE MAXIMIZATION UNDER TRANSMISSION CONSTRAINTS

$$\max \mathcal{S} = \sum_{j=1}^N \mathcal{B}_j(p_{B_j}) - \sum_{i=1}^M \mathcal{C}_i(p_{S_i})$$

*s.t.*

$$g_n(p_{S_1}, \dots, p_{S_M}; p_{B_1}, \dots, p_{B_N}) = 0$$

$\forall$  node  $n$

set of  
power  
flow  
equations

$$f_\ell(p_{S_1}, \dots, p_{S_M}; p_{B_1}, \dots, p_{B_N}) \leq f_\ell^{\max}$$

$\forall$  line  $\ell$

real  
power  
line flow  
limits

# CONGESTED LINE AND SYSTEM

---

- We call a transmission line  $\ell$  *congested* if the real power line flow violates the line limit, i.e., the corresponding inequality constraint becomes binding :

$$f_{\ell}(p_{S_1}, \dots, p_{S_M}; p_{B_1}, \dots, p_{B_N}) = f_{\ell}^{max}$$

- We call the transmission system *congested* if there are one or more *congested* lines in the network

# CONGESTION

---

- ❑ Power system reliability considerations require secure operations not only under base case conditions but also under the set of postulated contingency cases
- ❑ Congestion occurs if one or more limit violations are detected either under the base case or in any of the contingency cases
- ❑ The incorporation of transmission considerations requires the representation of the base case *and* all the postulated contingency cases

# THREE-BUS SYSTEM: TRANSMISSION UNCONSTRAINED DISPATCH

---

- ❑ The transmission unconstrained dispatch is infeasible because the line flow  $f_{13}$  violates limit  $f_{13}^{max}$
- ❑ The net injections at buses 1 and 2 have to be modified to drive the network to feasibility
- ❑ The only choice of buyer  $B_3$  is to bid sufficiently high to induce seller  $S_3$  to provide supply to meet his load

# THREE-BUS SYSTEM: ENSURING TRANSMISSION FEASIBILITY

$$\frac{2}{3} \cdot (300 - x) + \frac{1}{3} \cdot (200 - 2x) = 200 \text{ MW} \rightarrow f_{13}^{\max}$$

# THREE-BUS SYSTEM: REDISPATCH OF SUPPLY

---

- $x$  is the amount of redispatch due to the impacts of the  $f_{13}^{max}$  constraint on seller  $S_1$
- $2x$  is the amount of redispatch due to the impacts of the  $f_{13}^{max}$  constraint on seller  $S_2$
- Redispatch calculation:

$$\frac{2}{3} \cdot (300 - x) + \frac{1}{3} \cdot (200 - 2x) = 200 \text{ MW}$$

so that

$$x = 50 \text{ MW}$$

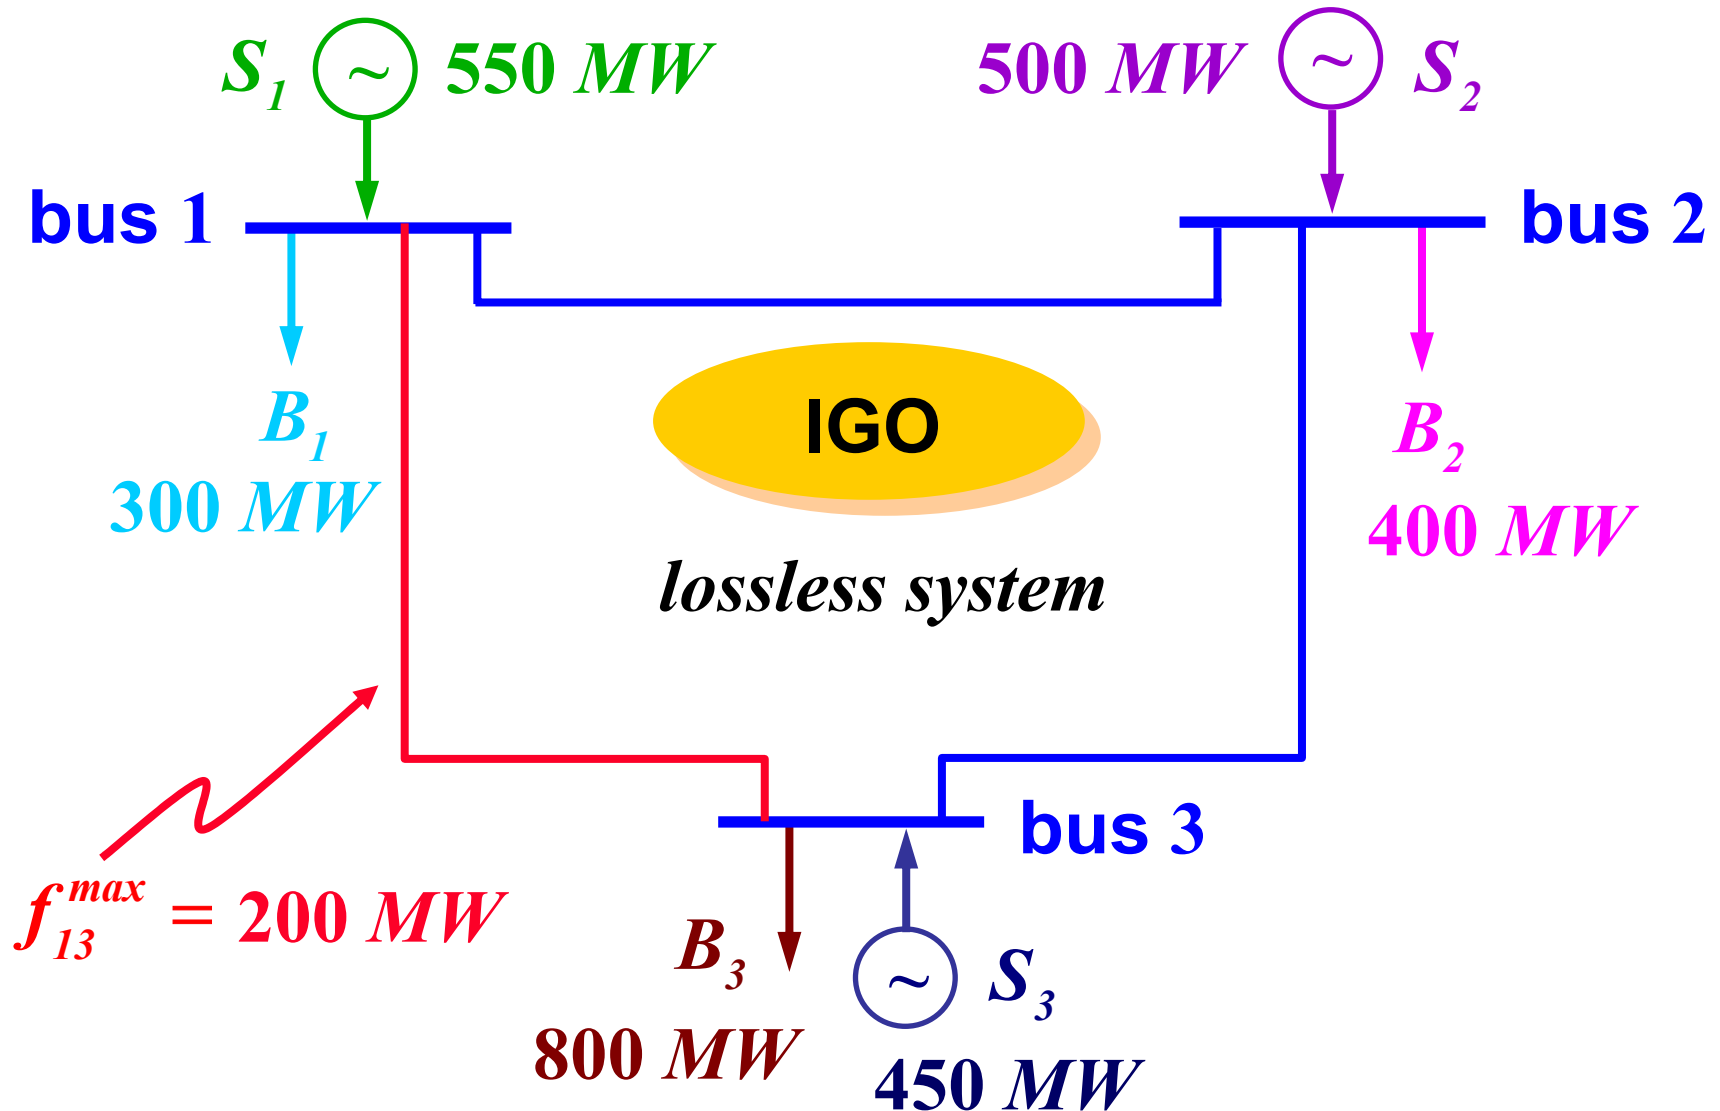

# THREE-BUS SYSTEM: REDISPATCH OF SUPPLY

---

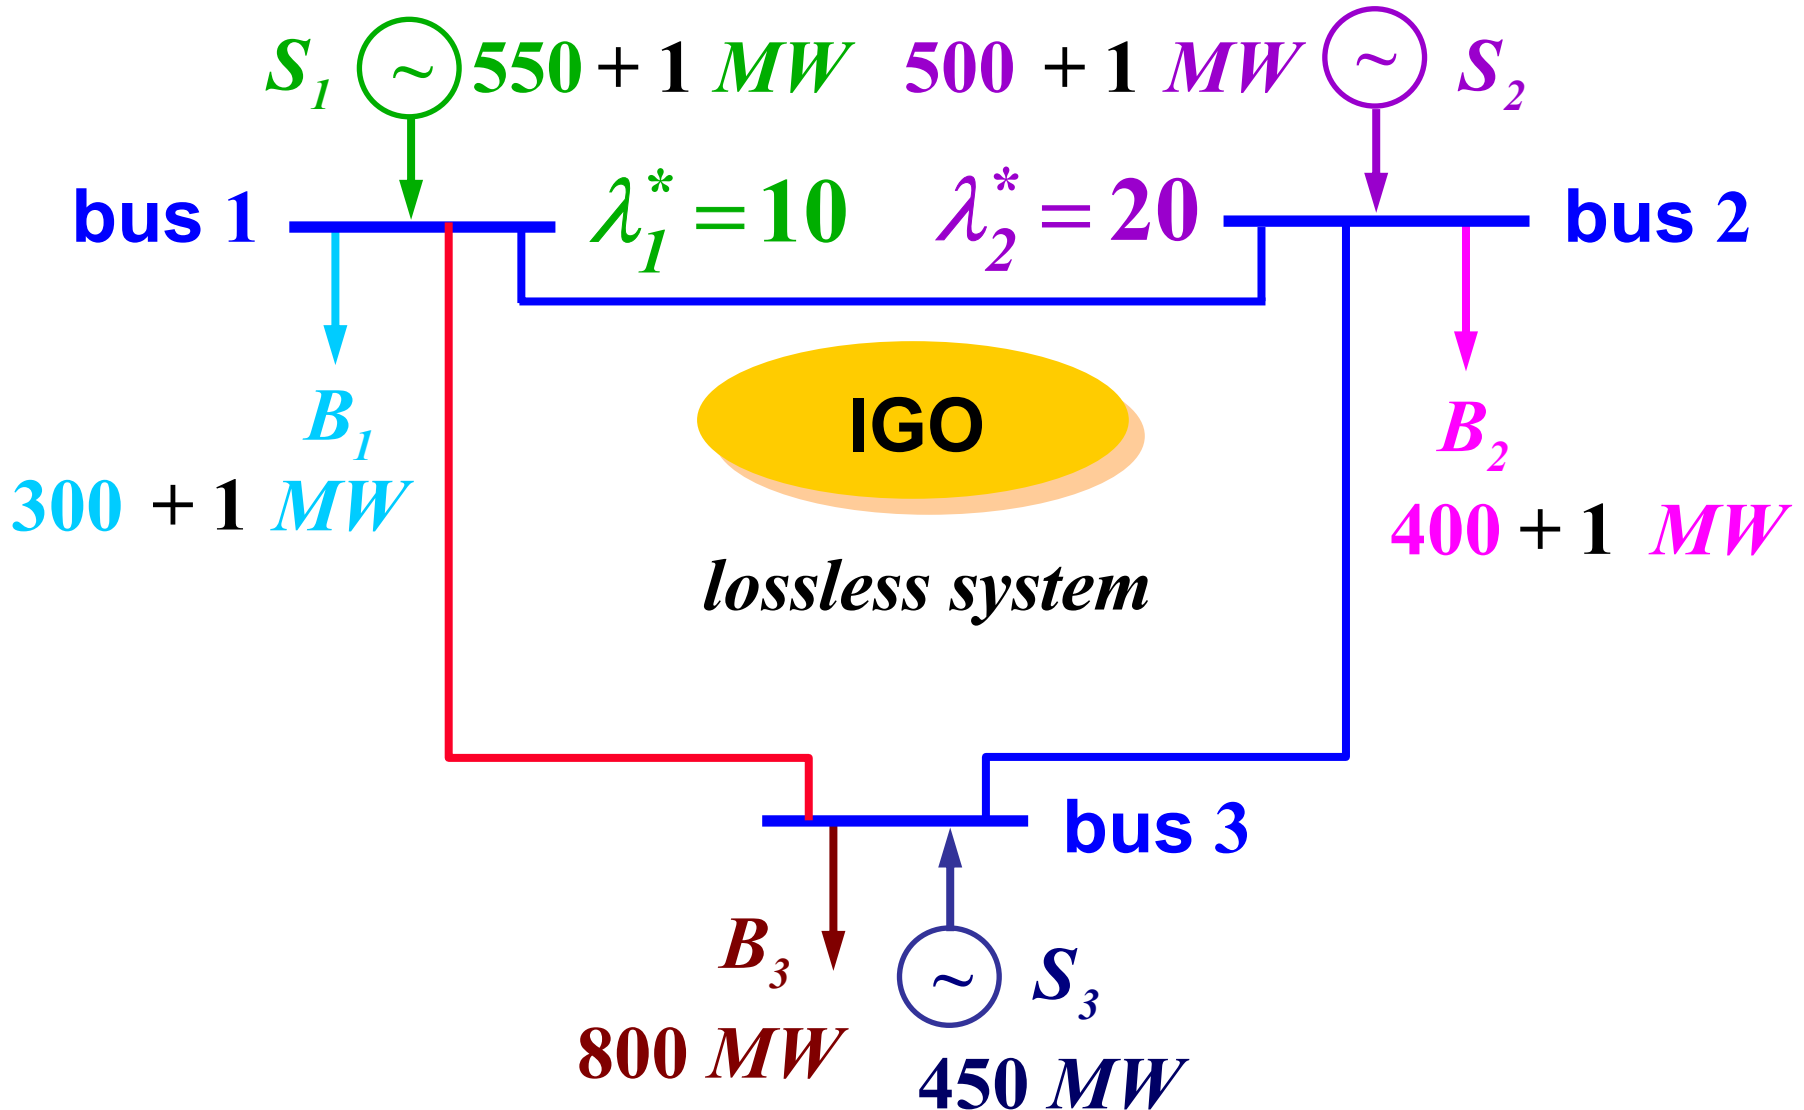

- ❑ Then, the IGO reduces the output of seller  $S_1$  by  $50 \text{ MW}$  and that of seller  $S_2$  by  $100 \text{ MW}$
- ❑ Since there is a willingness to pay by the buyer  $B_3$ , the IGO increases the output of seller  $S_3$  by  $150 \text{ MW}$
- ❑ The constrained dispatch changes the output of each seller and may impact the load supplied to buyer  $B_3$

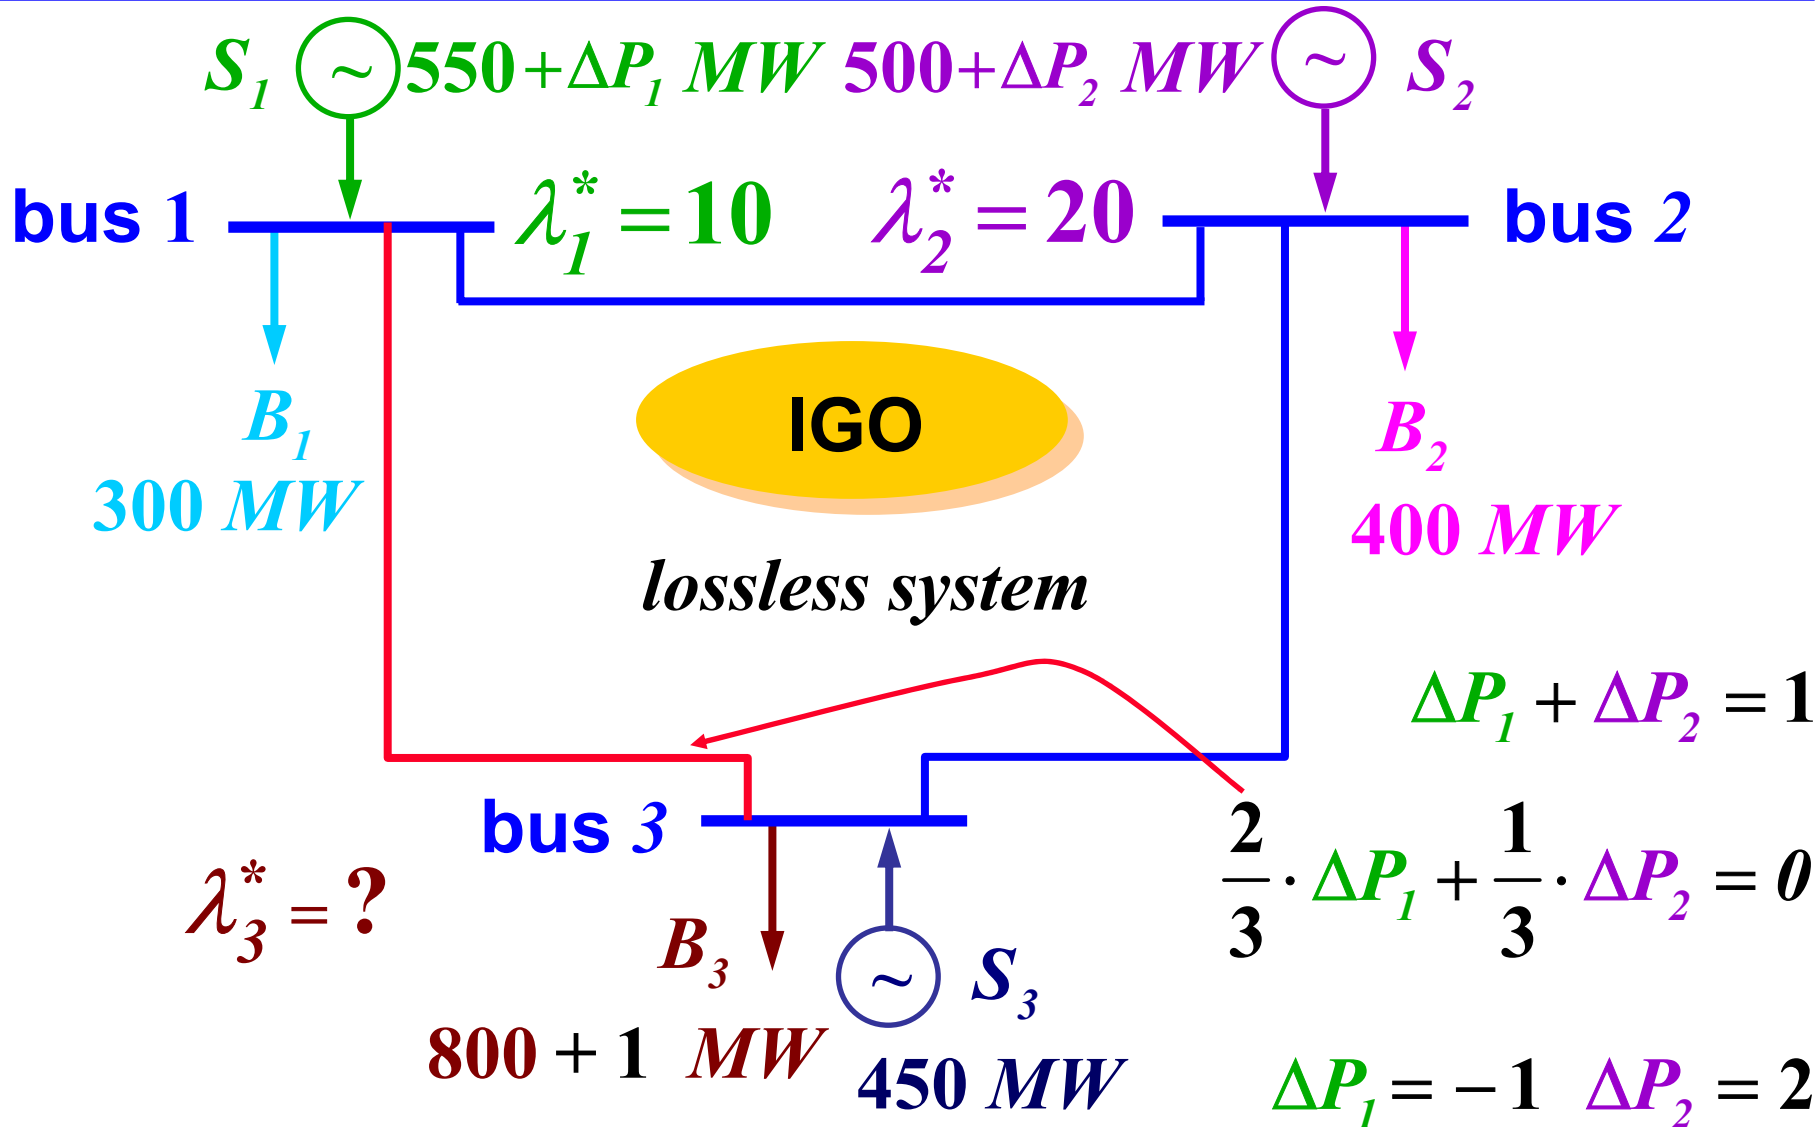

# THREE-BUS SYSTEM: TRANSMISSION CONSTRAINED DISPATCH

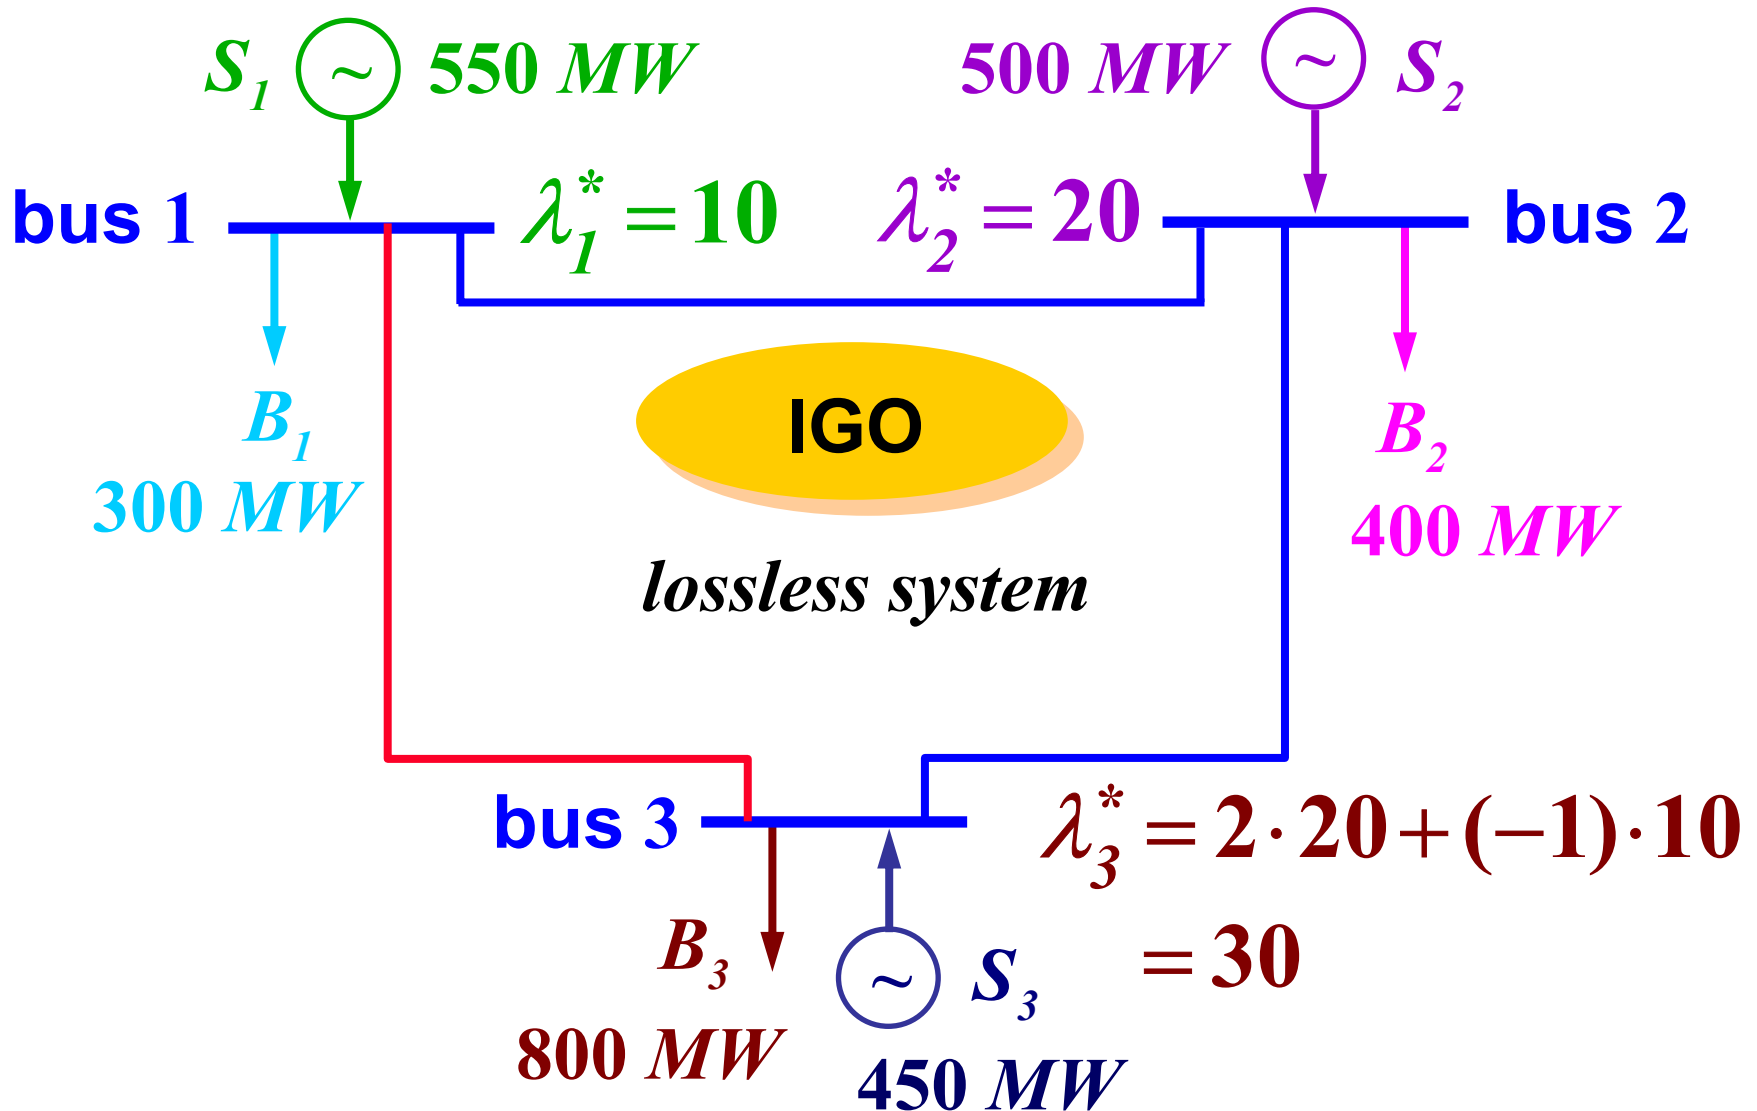

# THREE-BUS SYSTEM: $LMPs$

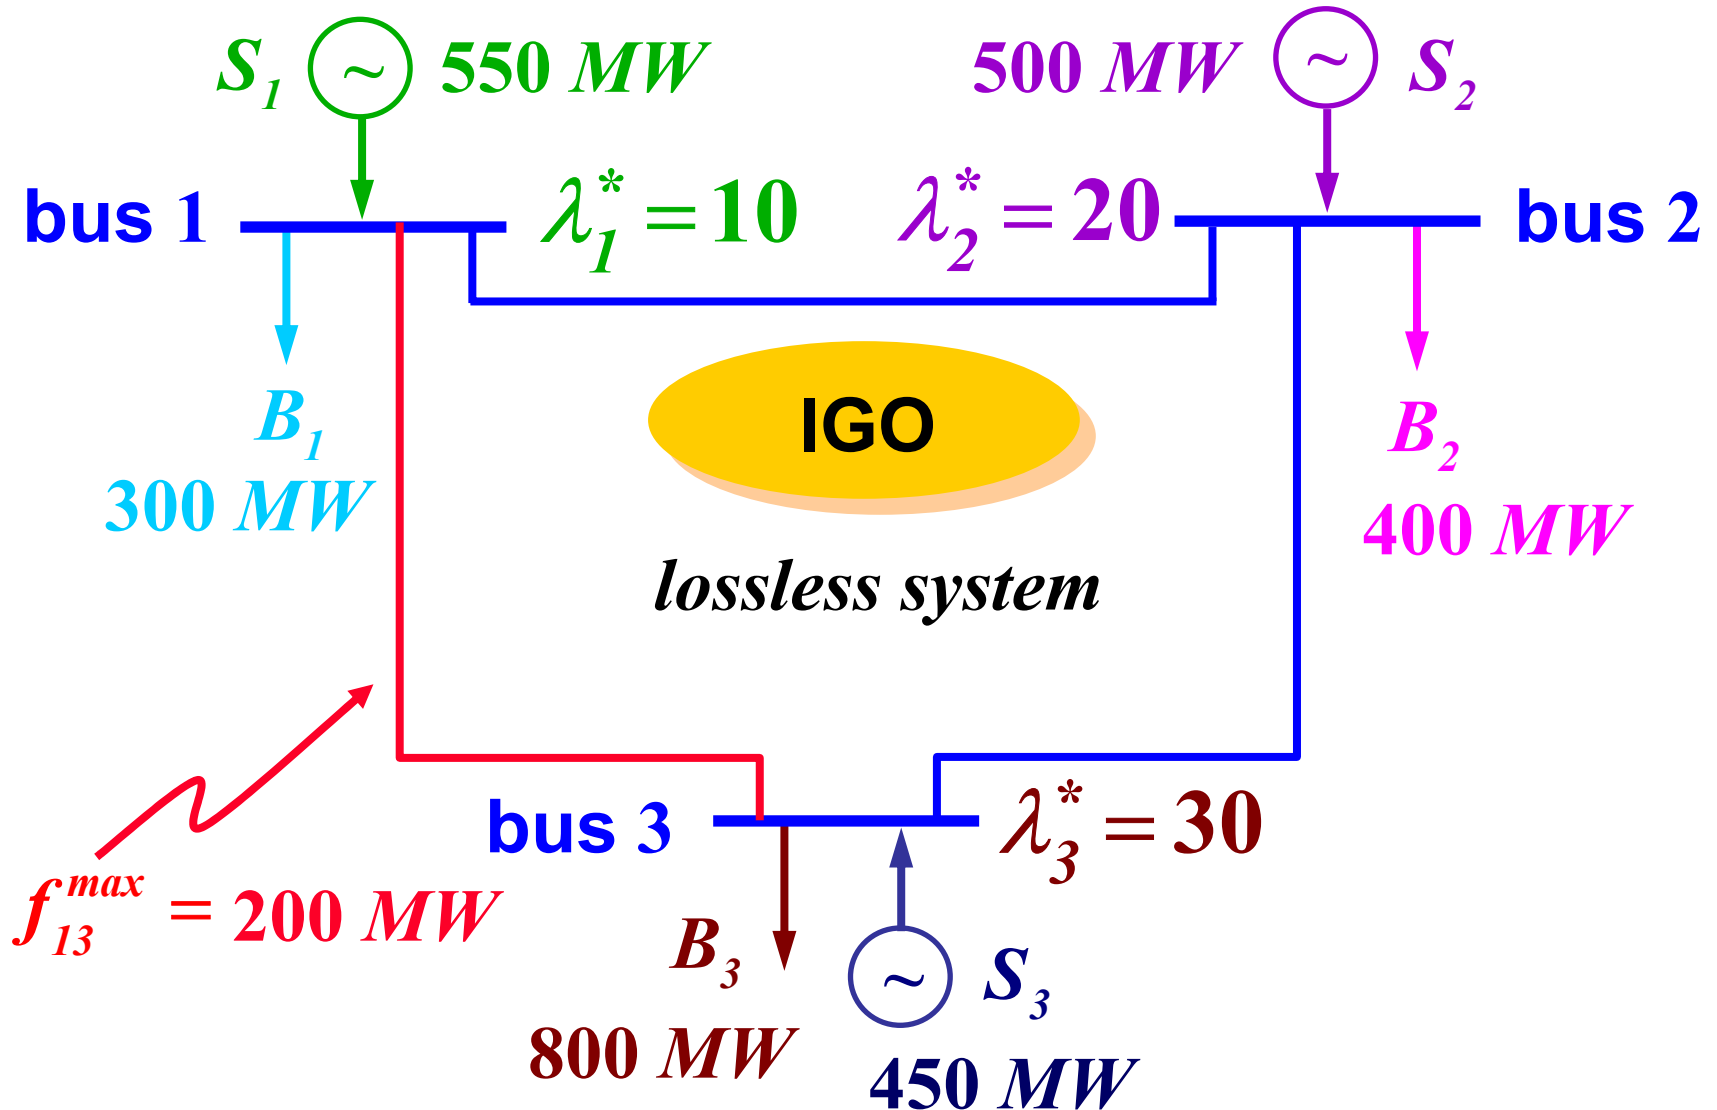

# THREE-BUS SYSTEM: $LMPs$

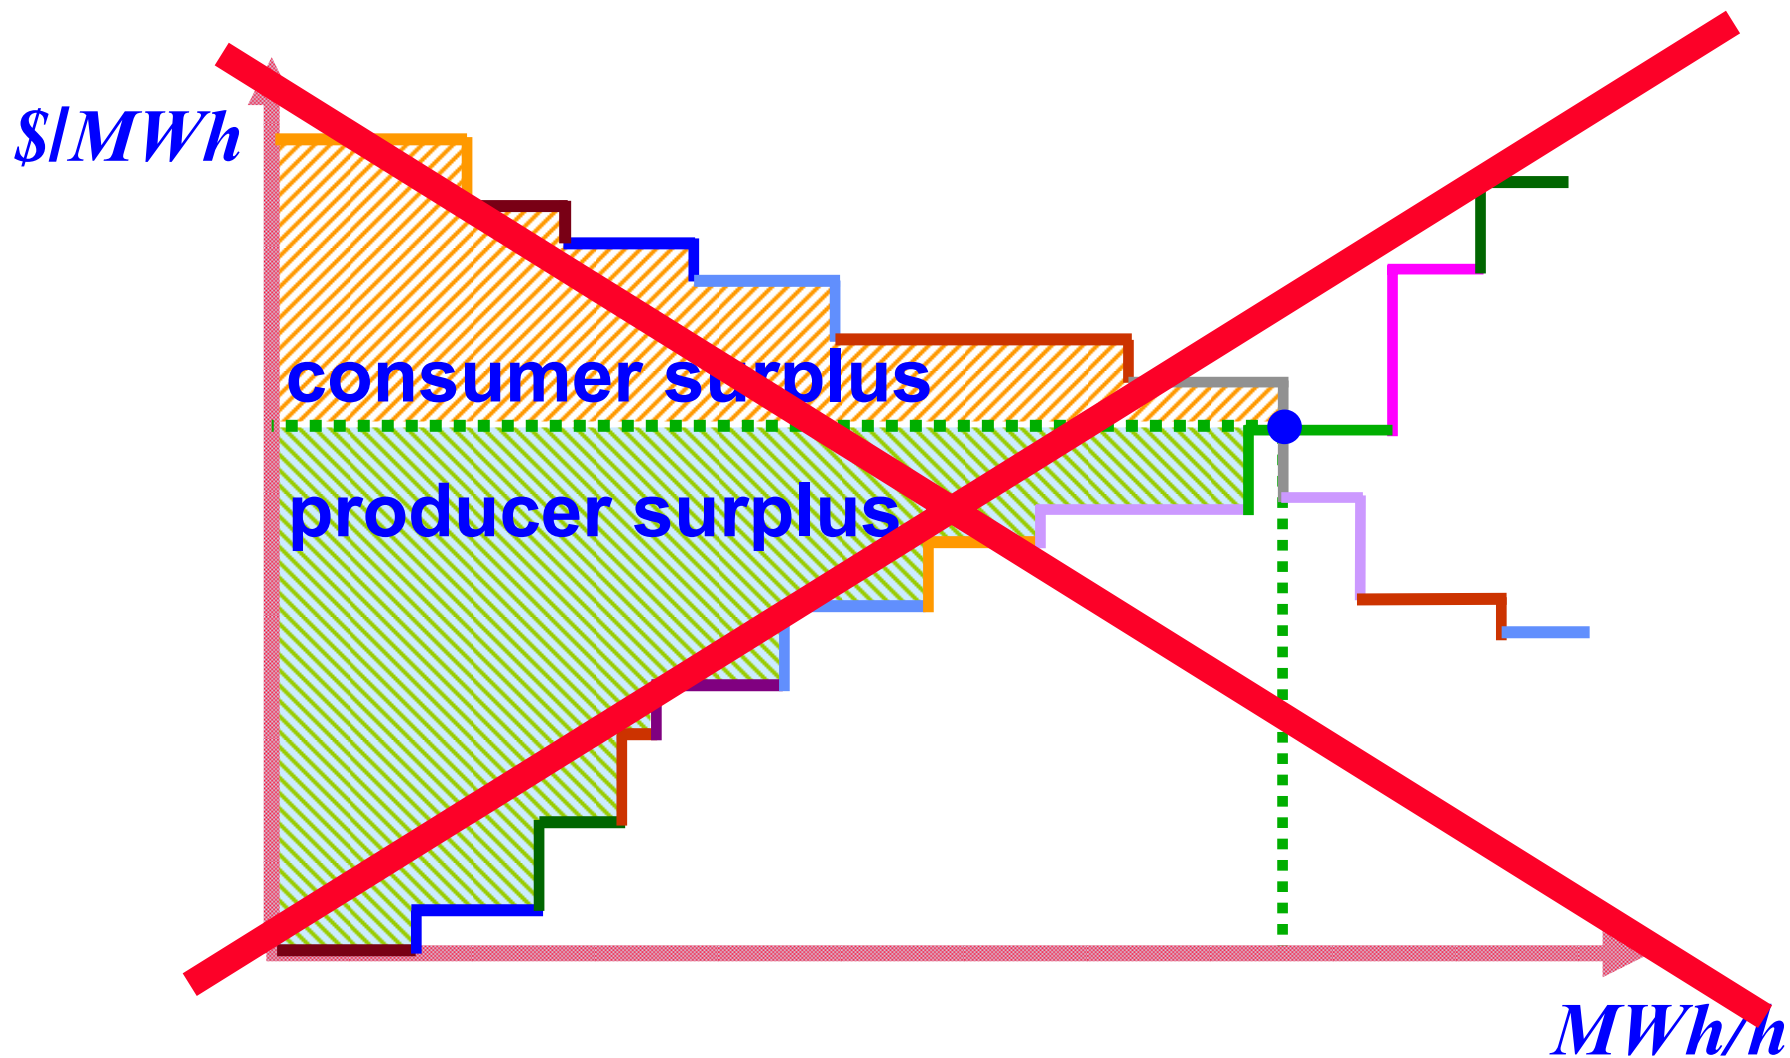

# THREE-BUS SYSTEM: $LMPs$

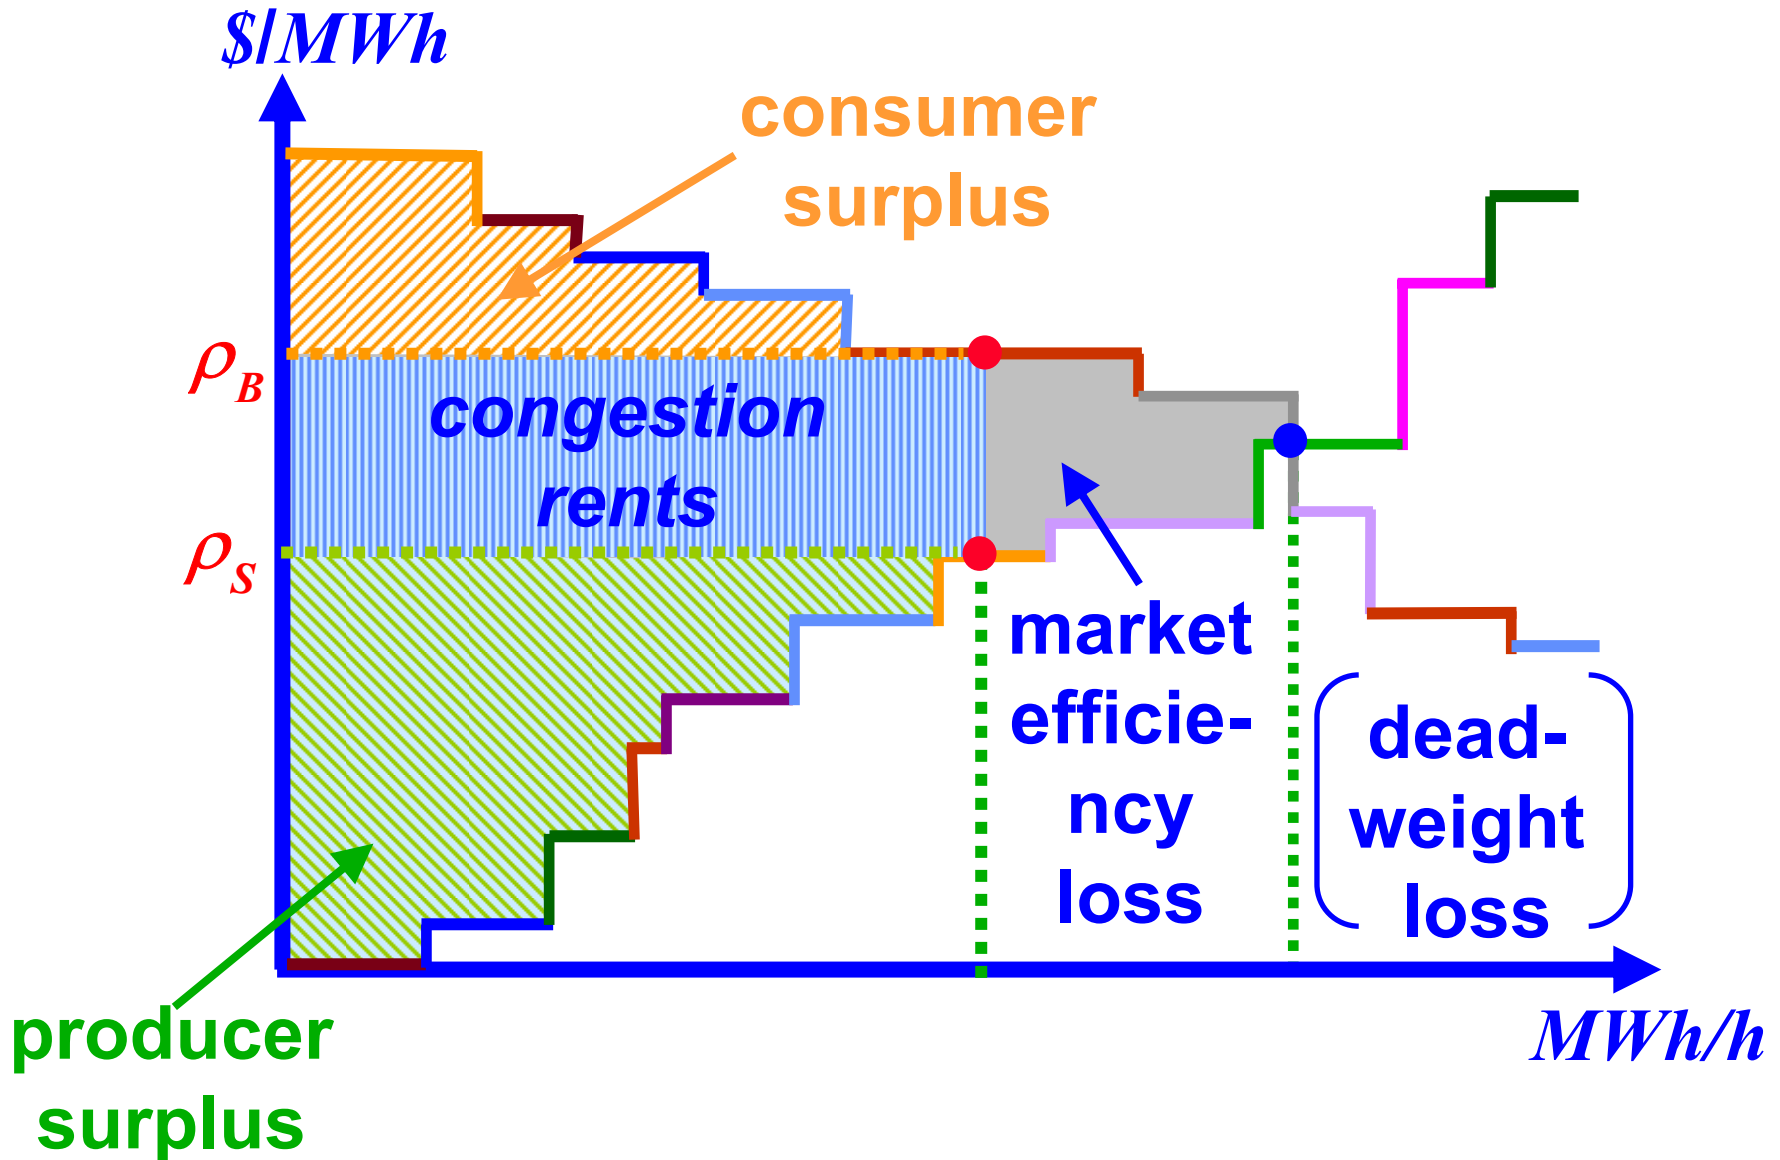

# THREE-BUS SYSTEM: $LMPs$

# SOCIAL WELFARE AND SURPLUSES

# SOCIAL WELFARE AND SURPLUSES

# IMPACTS OF CONGESTION

---

- ❑ Congestion in the system leads to a change from the single market equilibrium point to different nodal equilibrium points
- ❑ Change in the preferred schedule for the required generation – demand balance may lead to possible curtailment in production or consumption
- ❑ The individual surpluses of the players change from the unconstrained market values to those in the markets at each bus under constrained conditions

# CONGESTION MEASURES

---

- The impacts of congestion may be measured in terms of the energy that needs to be redispatched and/or the financial costs on the various players
- Measures of congestion impacts in \$
  - redispatch costs
  - *congestion rents*
  - market efficiency loss

# CONGESTION RENTS

- In the constrained case we have different prices at the different zones, so the players may face different clearing prices depending on their locations
- The social welfare in this case is given by

$$\hat{\mathcal{J}} = \hat{\mathcal{J}}^S + \hat{\mathcal{J}}^B + \left( \sum_{j=1}^N \rho_j \cdot p_{B_j} - \sum_{i=1}^M \rho_i \cdot p_{S_i} \right)$$

**congestion rents  $\kappa$**

# CONGESTION RENTS

---

- In the constrained case, the *congestion rents* are part of the social welfare

$$\hat{\mathcal{J}} = \hat{\mathcal{J}}^B + \hat{\mathcal{J}}^S + K$$

- The *congestion rents* are also known as *merchandising surplus* and correspond to the difference between the amounts paid by buyers and the amounts received by sellers; the *congestion rents* are collected by the IGO

# MARKET EFFICIENCY LOSS

- ❑ Congestion may produce a reduction in the social welfare of the market due to the physical network constraints
- ❑ This reduction is called *market efficiency loss* and is defined by

market efficiency loss

constrained social welfare

$$\mathcal{E} = -\left(\mathcal{S} \Big|_c - \mathcal{S} \Big|_u\right)$$

- ❑ In economics, the *market efficiency loss* is also known as *deadweight loss*

# THREE - BUS SYSTEM: MARKET EFFICIENCY LOSS

---

- For the unconstrained case we have

$$\mathcal{S} \Big|_u = 265,600$$

- For the constrained case we have

$$\mathcal{S} \Big|_c = 263,750$$

- The *market efficiency loss* is

$$\mathcal{E} = -\left(\mathcal{S} \Big|_c - \mathcal{S} \Big|_u\right) = 1,850$$

# THREE – BUS SYSTEM: CONSTRAINED CASE

| seller                | surplus (\$) | buyer   | surplus (\$) |
|-----------------------|--------------|---------|--------------|
| $S_1$                 | 1,500        | $B_1$   | 16,000       |
| $S_2$                 | 2,000        | $B_2$   | 20,000       |
| $S_3$                 | 2,250        | $B_3$   | 216,000      |
| total                 | 5,750        | total   | 252,000      |
| congestion rents (\$) |              | 6,000   |              |
| social welfare (\$)   |              | 263,750 |              |

# CAUSES OF SOCIAL WELFARE REDUCTION

---

- The redispach of higher-priced units to replace the output of the lower-priced generation
- The decrease in market efficiency
- The decrease in the producer surplus of some sellers
- The decrease in the consumer surplus of some buyers
- The needs for ancillary services provided by sellers charging higher prices
- The creation of situations that may lead to the exercise of market power

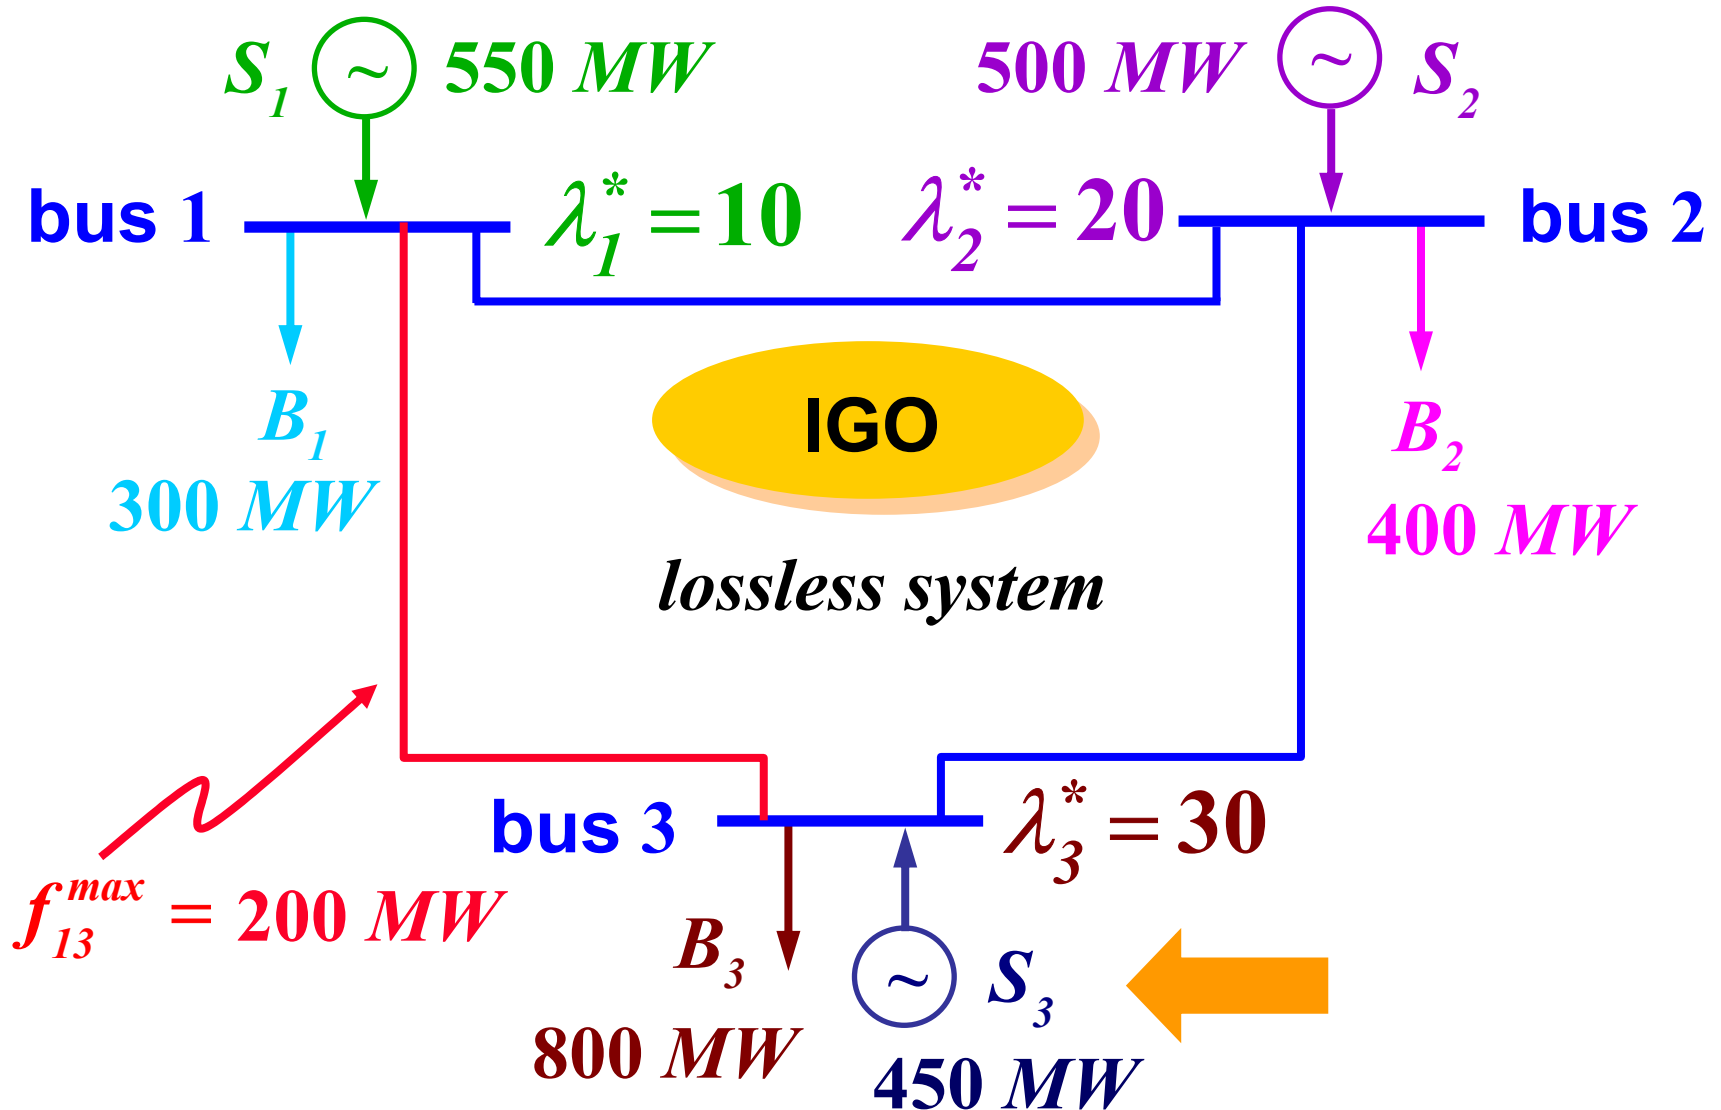

# ADDITIONAL CONGESTION IMPACTS

---

- Increase of costs for delayed connection of new generation
- Reduction in reliability
- Pollution from older and less efficient plants that must be operated only for reliability purposes

# THREE-BUS SYSTEM: $LMPs$

# SENSITIVITY STUDY IN THE THREE - BUS SYSTEM

---

- We investigate the impacts of changing the offer of seller  $S_3$  for his second block by varying the offer price from 29 to 330  $\$/MWh$ ; the other offers/bids remain unchanged
- We evaluate the resulting surpluses for the various values of the offers submitted

# THREE-BUS SYSTEM: $\lambda_3^*$ AND $\mathcal{P}^{S_3}$

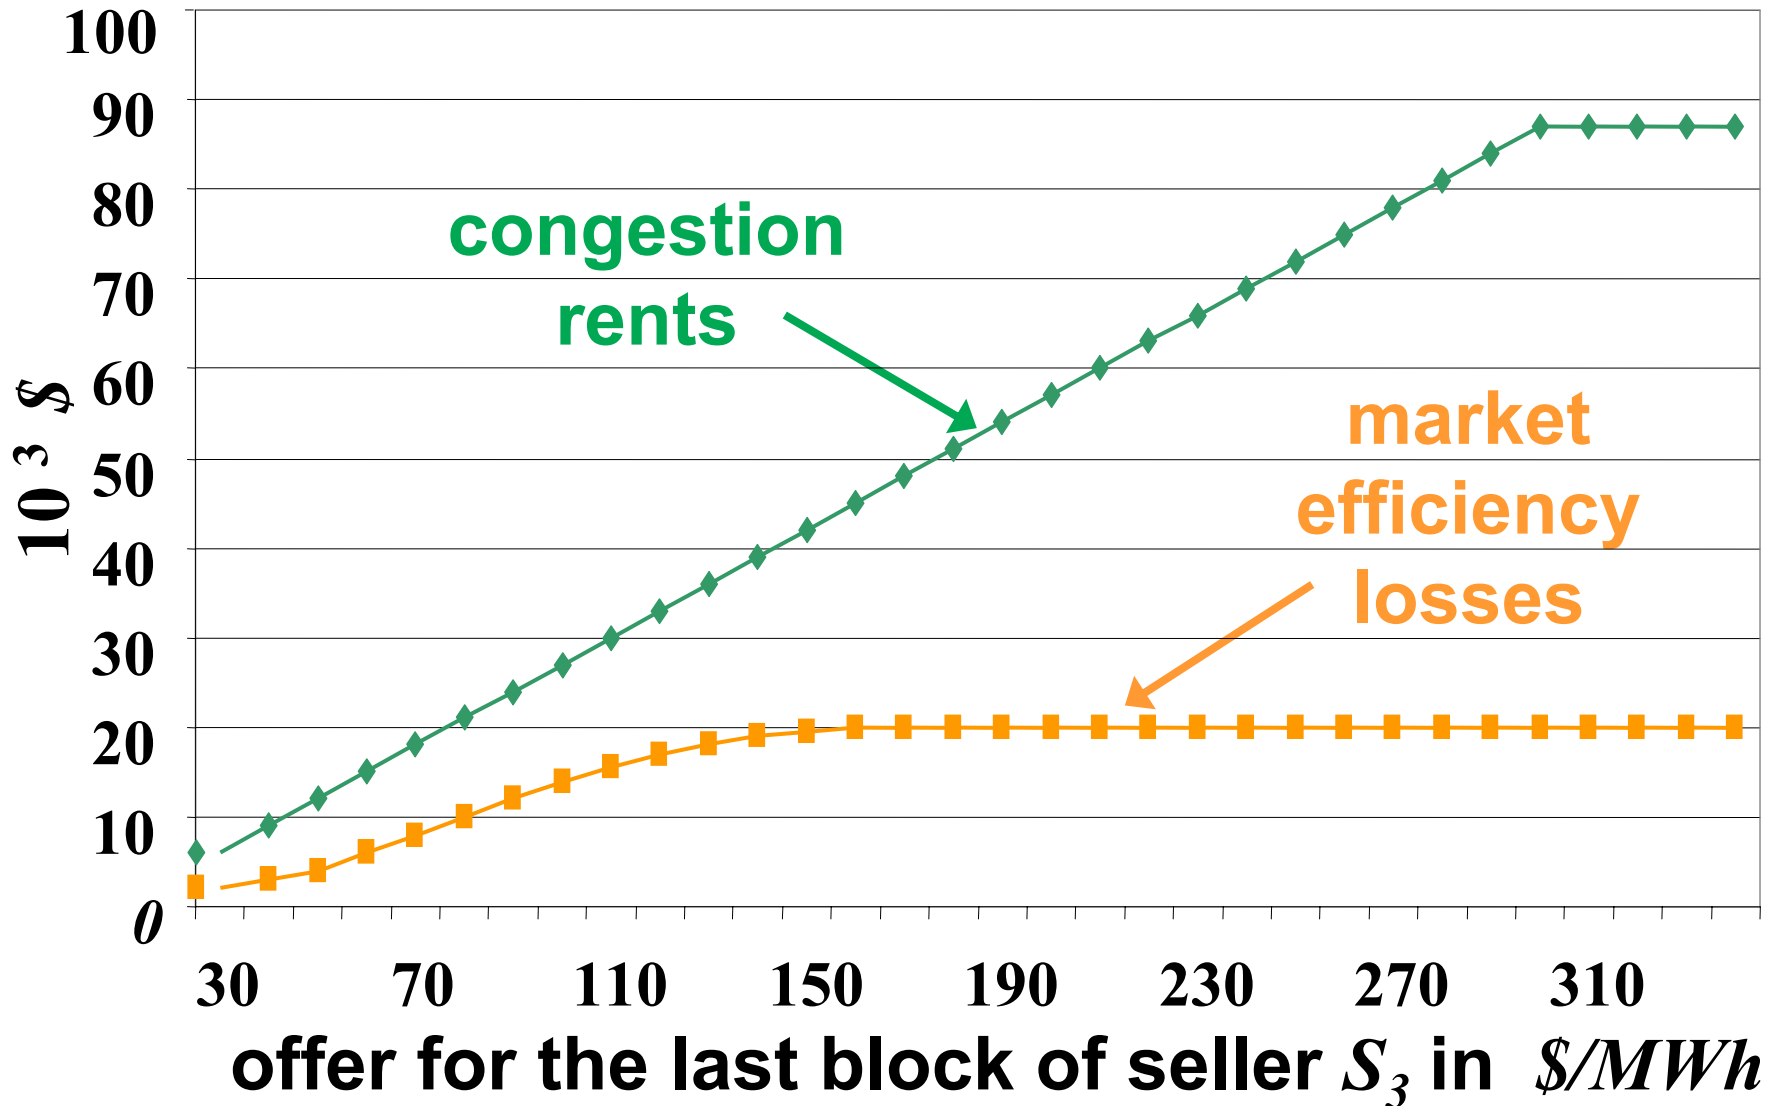

# THREE-BUS SYSTEM: PRODUCER SURPLUS

# THREE-BUS SYSTEM: CONSUMER SURPLUS

# THREE-BUS SYSTEM: MARKET PERFORMANCE MEASURES

# LOCAL MARKET POWER

---

- ❑ **Market power is the ability of a firm to profitably raise the price of a product**
- ❑ **The exercise of market power may be carried out by:**
  - **the physical withholding of units**
  - **the financial withholding of units**
- ❑ **Transmission constraints may create locational market power since they may set up area markets with limited importing capability**

# SIMULATION STUDIES

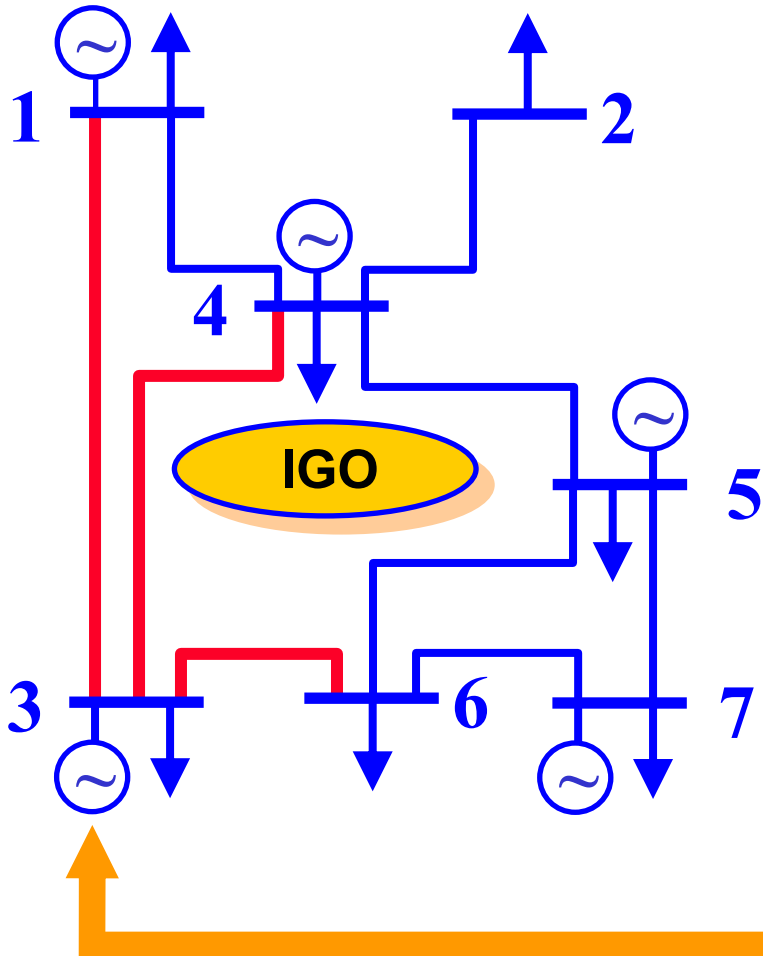

---

- ❑ A seller changes his offer prices by varying the offer price for the last block offered
- ❑ We study the resulting variations of the producer surplus, consumer surplus, *congestion rents* and *market efficiency loss*
- ❑ The simulations performed on different systems of various sizes are reported

# THE SEVEN-BUS SYSTEM EXAMPLE

— constrained line

| offers |        |        |
|--------|--------|--------|
| $S_1$  | 200@5  | 600@10 |
| $S_3$  | 200@40 | 100@60 |
| $S_4$  | 200@10 | 300@15 |
| $S_5$  | 100@20 | 300@40 |
| $S_7$  | 200@30 | 200@40 |

| bids  |         |         |
|-------|---------|---------|
| $B_1$ | 100@80  | 100@50  |
| $B_2$ | 200@100 | -       |
| $B_3$ | 800@500 | -       |
| $B_4$ | 200@140 | 200@120 |
| $B_5$ | 100@80  | 200@50  |
| $B_6$ | 200@120 | 200@110 |
| $B_7$ | 100@90  | 100@50  |

# SEVEN-BUS SYSTEM: PRODUCER SURPLUS

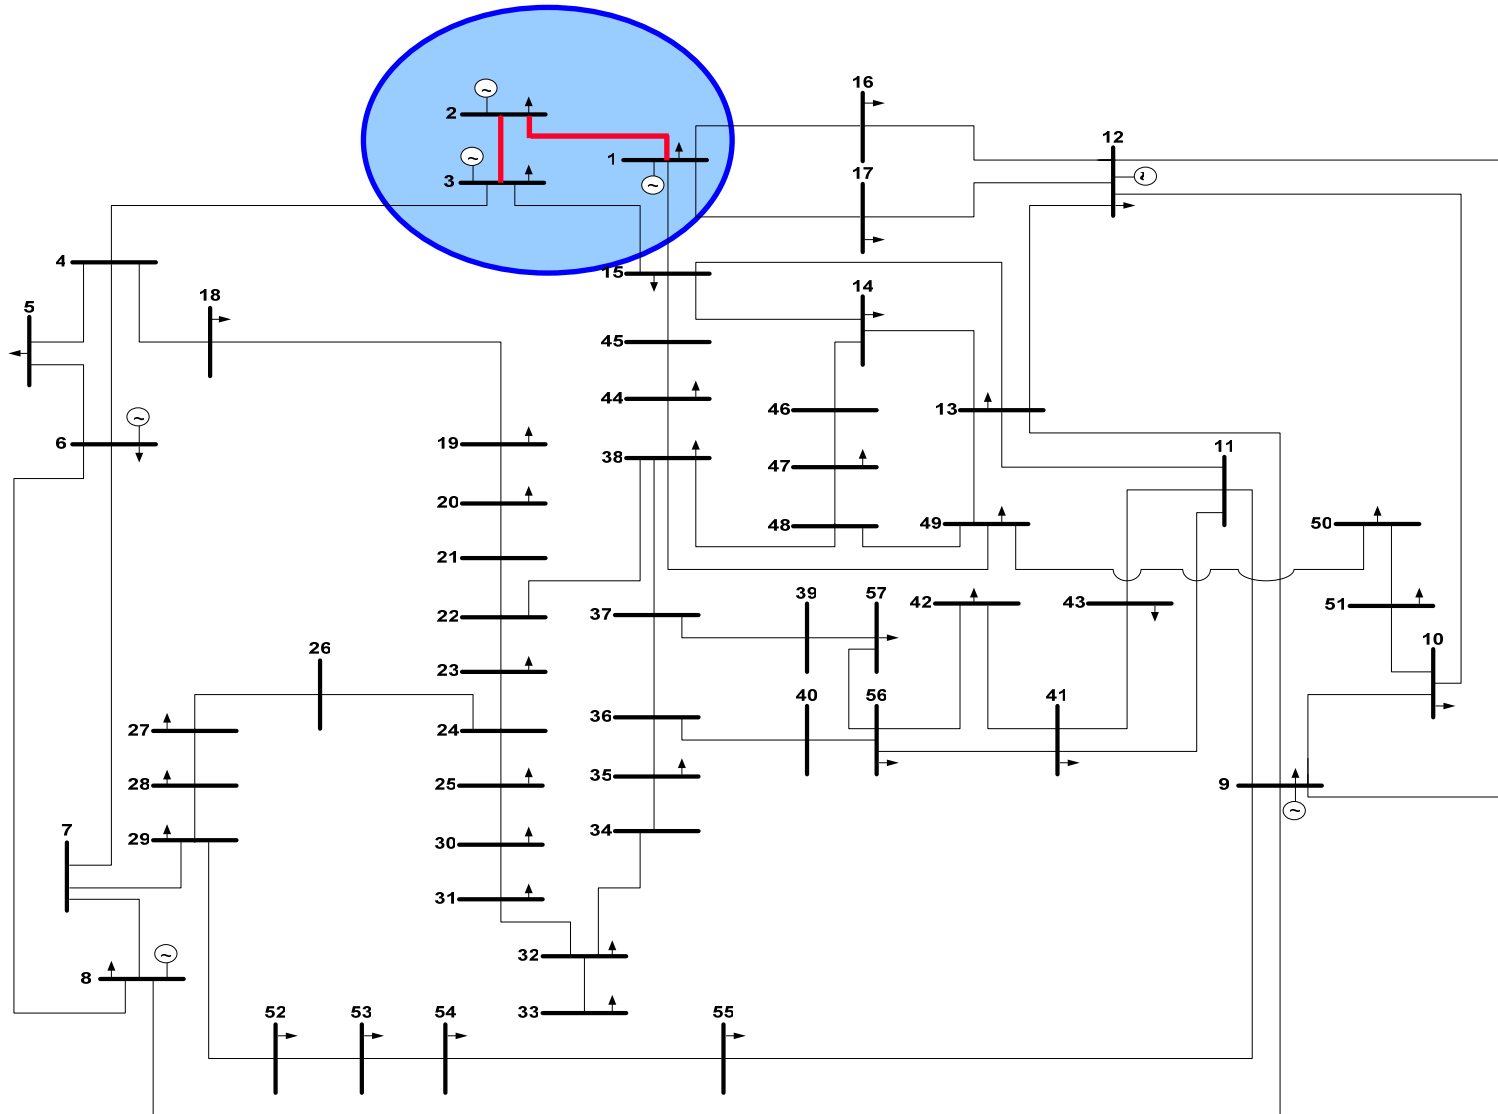

# SEVEN-BUS SYSTEM: CONSUMER SURPLUS

# SEVEN-BUS SYSTEM SENSITIVITY

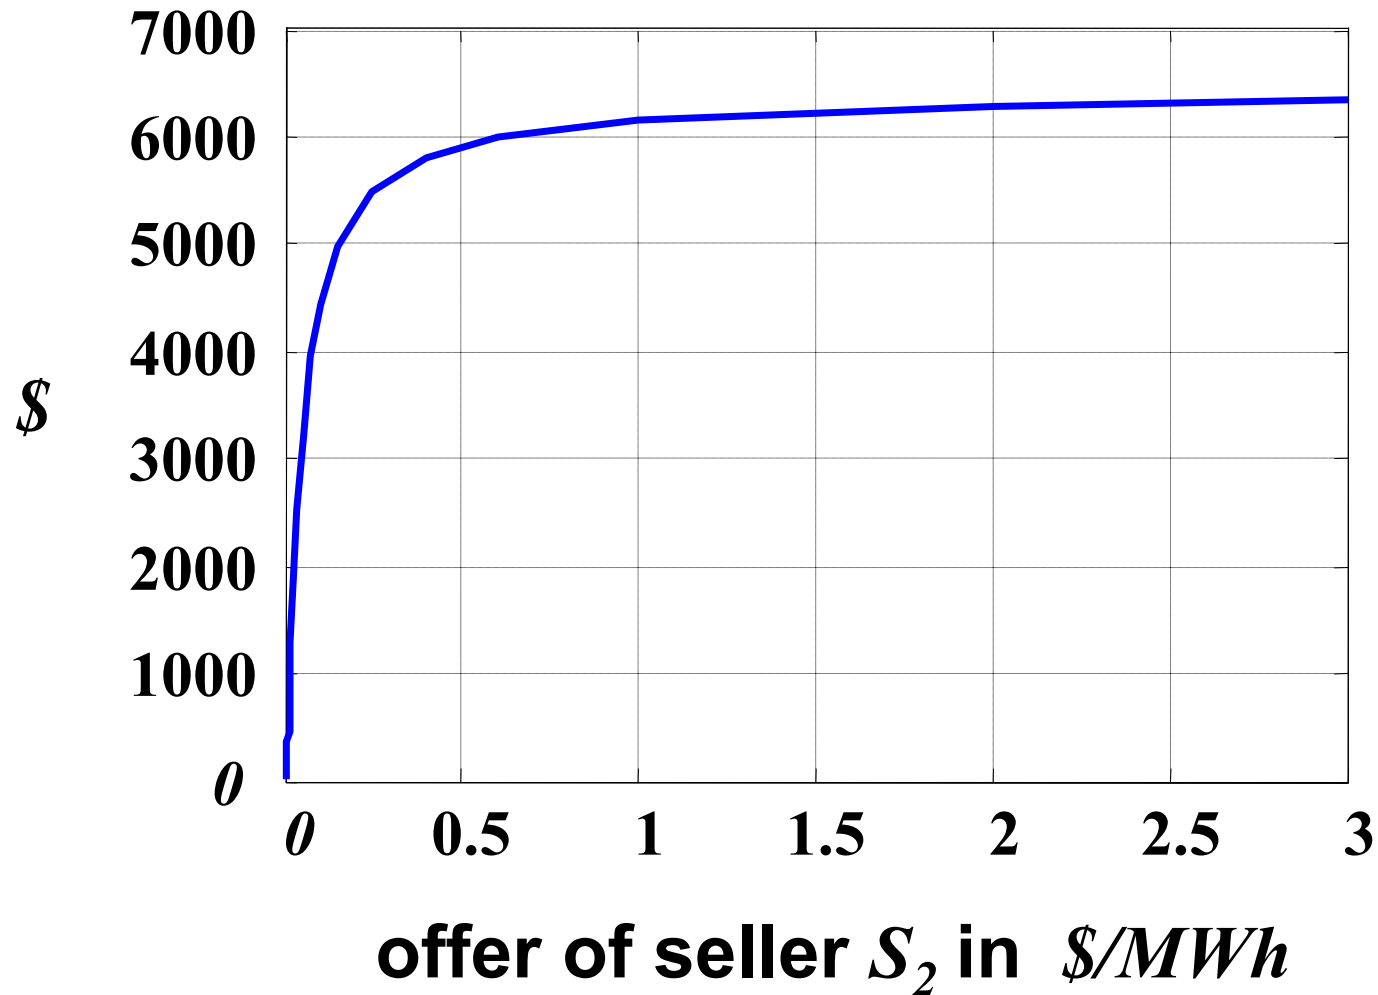

# THE 57-BUS SYSTEM

# THE 57-BUS SYSTEM: CONGESTION RENTS

# THE 57-BUS SYSTEM: MARKET EFFICIENCY LOSS

# SIMULATION RESULTS

---

- ❑ Congestion situations produce, typically, changes in the consumer and social surpluses, the additional *congestion rents* component of the *social welfare*, and the market efficiency loss with respect to the unconstrained case
- ❑ Congestion creates situations which are conducive to the exercise of market power
- ❑ Under price-responsive demand, when a particular seller increases his offer prices, the impacts of congestion on the individual players and the entire market are bounded due to the asymptotic nature of the outcomes

# SIMULATION RESULTS

---

- ❑ We observe the existence of *free-riders* in the market on both the supply- and demand-sides
- ❑ There are also players that are negatively impacted by the exercise of market power
- ❑ The simulations underline the critical role of the network topology and the relative location of the market players in determining who are the losers and the gainers as a result in such a market power exercise attempt

# RTO CONGESTION COSTS

CAISO data excludes intra-zonal congestion ISO-NE data represents mitigated congestion costs

# FUTURE WORK

---

## □ Modeling

- incorporation of real power losses
- detailed representation of additional constraints
- incorporation of contingency case analysis

## □ Parametric analysis

- demand-side variation
- multiple players variation of offer/bid prices

## □ Study of the *market efficiency loss composition*
